EXTRACT

From an Act prescribing Rules for the Government of the State Library,
passed March 8th, 1861.

SECTION 11. The Librarian shall cause to be kept a register of all books issued and returned; and all books taken by the members of the Legislature, or its officers, shall be returned at the close of the session. If any person injure or fail to return any book taken from the Library, he shall forfeit and pay to the Librarian, for the benefit of the Library, three times the value thereof; and before the Controller shall issue his warrant in favor of any member or officer of the Legislature, or of this State, for his per diem, allowance, or salary, he shall be satisfied that such member or officer has returned all books taken out of the Library by him, and has settled all accounts for injuring such books or otherwise.

SEC. 15. Books may be taken from the Library by the members of the Legislature and its officers during the session of the same, and at any time by the Governor and the officers of the Executive Department of this State, who are required to keep their offices at the seat of government, the Justices of the Supreme Court, the Attorney-General, and the Trustees of the Library.

Mechanical Ore Concentration and Separation—No. 16.

[Written for the Press by FRANCIS M. F. CAZIN, M. E.,
Santa Fe, Mexico.]

Regulation of the Plunger.

As all sizes do not require the same amount of upward vertical stream or lift, and as by experience it has been ascertained that different sizes do require a different speed in the repetition of these lifts, I will give the rule for regulating lift of plunger and their number per minute, being the number of revolutions of the driving pulley. This rule is: the coarser the size the higher the lift; the finer the size the quicker the motion should be. One millimeter size works well with 120 strokes per minute. The limit for the lift is recognized by observing the overflow from one sieve to the other. This overflow should allow the particles of ore or rock to pass freely over the partitions without sticking to their top edge. The machinery of the automatic continuous one-plunger jig is so arranged as to allow a change of lift from one-eighth of an inch to two inches and a half lift, and the safest as well as easiest way to determine on the proper lift with this easy regulation is to test it. An easy, quiet flow, without jumping and splashing of the surface of the water, is a strong indication of an appropriate lift. The limits within which the machine permits variation have been determined by theory as well as practice, but the balance practice would do. Nevertheless, it may be interesting to the practical man also to ascertain how theory and practice have to combine in order to reach the result of success. I therefore indulge here in a specimen of the theory.

Table

Showing the speed of vertical stream of water required in order to keep in suspension therein round particles of galena, iron pyrites and quartz of different diameter:

MINERAL.	Diameter in Millimeters.	Speed in Meters per Second.									
		10	8	6	4	3	2	1	1	1	1
Galena.....	7.5	1.31	1.17	1.02	0.83	0.72	0.59	0.41	0.29		
Iron Pyrites.....	5.0	1.05	0.92	0.79	0.65	0.56	0.46	0.32	0.25		
Quartz.....	2.6	0.63	0.56	0.49	0.40	0.35	0.24	0.20	0.14		

A round particle of galena, two millimeters or one-twelfth inch in diameter, will be kept in suspension in a vertical upward water stream, having a speed of 590 millimeters per second or 35,400 millimeters per minute. Supposing plunger and sieve to be of equal size, and 120 full strokes or 240 half strokes per minute, each half stroke should theoretically measure 147 millimeters, or nearly six inches. Now, practice proves that with 120 full strokes a minute, two millimeters galena will not only be suspended but be raised by a lift of five-eighths of an inch or 15 millimeters. The material resting on the sieves and intercepting the water, therefore acts so as to accelerate the stream produced by the plunger to twenty times its original speed, allowing only one volume of water to be present when 19 volumes of material are raised. But practice again proved that five times the height of lift is the proper amount of material on the sieves; it shows that only one-quarter part of the volume of water is active in the vertical stream at the time within the material and the other three-quarters either approaching from below, or flowing over with the horizontal stream. Once these figures established, the consequences for other sizes and materials can be drawn from the above table. Thus it takes half the speed to keep quartz suspended, or the same speed will carry it double the distance; or it takes four to five times the size of quartz for one of galena to remain together on the sieves and not to separate. This peculiar motion has produced such close and excellent work as is produced by no other motion, either eccentric or elastic.

For the good reasons stated before I abstain to enter on a further detail concerning the special construction of the one-plunger jig, but let a correspondent of the New York Mining

Journal, a mining engineer from Freiberg, Saxony, deliver an opinion upon it (Vol. XVI, No. 24):

"All those who have had the opportunity to observe the working of mineral-dressing arrangements will, like me, appreciate the importance of the fact that the one-plunger jig, as it is, accommodates itself to all the emergencies and necessities occurring, not only by a variation in the quality of ore and percentage of valuable material, but also to the use of one and the same apparatus for treating different sizes. Moreover, the practical engineer will appreciate that all the motions in the machinery of the one-plunger jig are correct, and do not involve those small but frequently recurring irregularities, resulting in friction and wear, as in all jigs in which plungers are fastened in their center to an oscillating crank or an eccentric. There is no apparent reason why the velocity or number of lifts with such a regular and unimpeded motion should not be increased, there being no other limits to this than the consis-

The bed can be provided by covering the sieve bottom with a layer of gun-shot of a size a little larger than the meshes of the wire-cloth (sieve) and, indeed, a bed of gun-shot is recommendable on account of causing less wear and tear of sieves, than the immediate contact of mineral with less even surface than shot. With such a bed the jig will act properly right from the start of its motion.

In case no shot bed is provided the jig can only be made to work properly by letting the heavy parts accumulate so as to cover the entire bottom of the sieve.

BULLION SHIPMENTS.—Since our last issue shipments from the prominent mines have been as follows: Modoc, December 26th, \$5,500; total to date, \$88,090; Calaveras, 26th, \$1,700; Leopard, 28th, \$5,200; Tybo Con., 25th, \$10,245.65; total to date, \$47,671.75; Ophir, 28th, 3 bars—value, \$11,643.30; Manhattan, 26th, 12 bars—value, \$12,404.40; California, 28th, 38

KEMP'S IMPROVED BOILER CLEANER.

tency of the material out of which the parts are constructed."

In working this or any other jig certain points are to be observed in order to procure satisfactory results. I will mention them here.

The stroke (by screw passing lengthways through the revolving crank and wrist) and the entire number of revolutions being properly regulated, work may begin. It is here to be stated that the crank, *p*, should describe the upper part (two-thirds approximately) of its revolution when the oscillating crank, *i*, with the rod, *j*, are raised, because thereby the stroke of plunger presses the water up through the sieve in (one-third) revolution and allows

The Bed on the Jig-Sieves.

When the work of the jiggling machine is begun the material on the sieve is mixed, as well as the ore in general. Thus light parts as well as heavy parts are lying immediately on the bottom of the sieve, and will lie directly on the bottom as long as there is not a sufficient amount of heavy material to cover the entire bottom of the sieve, the light parts continuing to drop after the heavy parts have reached the bottom. No useful effect can be attained unless there is on each sieve sufficient heavy substance to cover the entire sieve bottom. This at once proves the necessity of a bed of heavy material on each sieve of such size as will force it to remain there.

bars—value \$160,113.73; total to date, \$605,469.10; Con. Virginia, 28th, 25 bars—value, \$92,187.30; since dividend, \$190,740.68; Northern Belle, 26th, \$10,805.56; California, 30th, \$93,617.79—to date, \$699,086.89; Con. Virginia, 30th, \$25,209.47—since dividend, \$215,950.15; Chollar, 29th, \$6,474.33, 30th, \$8,012.06; Manhattan, 30th, \$14,800; Northern Belle, 28th, \$11,597.22—total to date, \$109,628.58; K. K. Con., 30th, \$4,000, total for December account, \$55,000; Manhattan, January 2d, \$13,400; Modoc, Dec. 30th, \$12,320; Con. Virginia, Jan. 2d, \$42,055.33—since dividend, \$258,005.48; California, Jan. 2d, \$98,546.74—total to date, \$797,633.63; Tybo Con., Dec. 28th, \$11,351.75—to date, \$59,023.50; Modoc, Jan. 1st, 232 bars, value, \$6,000—total for December, \$18,320; Northern Belle, Dec. 31st, \$14,567.27; Chollar, Jan. 2d, 6 bars, \$15,496.18; Justice, Dec. 16th, \$89,617; 25th, \$66,052, Jan. 2d, \$54,295—to date, \$209,964.

A DISPATCH from Salt Lake claims the mineral exports from Utah Territory in 1876 to be a little over \$6,000,000. Mr. Valentine's estimate places the product at \$5,207,519.

THE *Coso Mining News* says: The town of Cerro Gordo has lost its former prosperity. The streets seem almost deserted, and many business houses are closed.

Kemp's Boiler Cleaner.

From no cause arises more serious danger, annoyance or damage to steam boilers than from the accumulations of mud, even from the purest waters, necessitating a frequent cleaning; and from the formation of scale upon tubes, flues or bolts, leading to a burning and destruction of the iron; and when this extreme is not reached, leading to the consumption of largely increased quantities of fuel without corresponding benefits. The invention illustrated herewith has, after three years' test, demonstrated the feasibility of obviating all the annoyance, risk and expense arising from the deposit of mud, scale and sediment, even from the most turbid waters, or those most strongly impregnated, either with lime, magnesia, gypsum, or the many other mineral substances so often met with by those who use steam.

The automatic boiler cleaner and mud extractor acts upon the well known principle that all sediments in water arise first to the surface as a scum, when separated from a condition of solubility by the process of boiling. The experiment of drawing off this scum by a surface cock answered the purpose but partially, for the reason that the scum was constantly forming, while the surface cock could not constantly be kept in operation.

The boiler cleaner, on the contrary, is always at work, and the blowing-off process need be repeated only so often as experience shows an undue collection of sediment in the reservoir, *A*, which is situated on the arch wall, or other convenient point above the shell of the boiler. From the reservoir, pipes *D*, *B*, passing through the shell of the boiler, are arranged; *D*, being a straight pipe, terminating several inches below the water line, while the pipe *B* connects with a vertical pipe, to the ends of which are attached peculiarly shaped mouths, *C*, *C*, placed in such position as at all times to be partially submerged. When the water is heated, a current is at once established through the mouths, *C*, *C*, pipe *B*, and reservoir *A*, returning to the boiler through the pipe *D*, assisting the action of heat in agitating the water in the boiler and creating a current, which still further prevents the impurities from precipitating. The scum upon the surface is drawn into the mouths, *C*, and passes through the pipes, but reaching the reservoir the current expands and is partially broken, and the sediment and impurities at once deposit and may be drawn off at pleasure by the pipe *E*.

The removal of the sediment leaves the water free from that which would form scale, and, in case of old or very dirty boilers, it is found that when new deposits cease the water soon finds its way under existing deposits, and old scale drops freely to the bottom, leaving the iron perfectly uncoated. The invention has been thoroughly tested, and is fully warranted to do its work efficiently, and in no case have those who have used them withheld a certificate of their value to all who use steam. Indeed, so thoroughly have they commended themselves that unauthorized persons are found in many localities representing themselves as the inventors, or agents for the inventor. Our readers should beware of purchasing from any person not having due authorization from James F. Hotchkiss, Bay City, Michigan, sole owner of the patents, and from whom any further particulars may be obtained.

THERE was only one cloudy day last month, and for the first time within the memory of the oldest inhabitant it was a December without even a sprinkle of rain. The comparative temperature was fifty-three degrees, two degrees lower than in the corresponding months of the two previous years.

THE San Francisco mint coined over \$10,000,000 more in 1876 than in 1875. The total output since the mint commenced operations in 1854 is \$452,306,600.

THE flow of water at the bottom of the C. & C. shaft is very strong, averaging about 45 miner's inches measurement.

CORRESPONDENCE.

Mining, Etc., About Helena, M. T.

EDITORS PRESS:—As this is about the center of the Territory, and surrounded on all sides by mines from which a large revenue was derived, Helena soon got the start of her neighbors in population, which now numbers about 3,000, or not far from one-fifth of the entire Territory. In addition to the capitol, and a fine brick building for a public school, at present accommodating 350 pupils, there has just been finished a neat, substantial brick structure to be used as a Government assay office, at a cost of \$50,000, under the charge of Mr. C. Rumley, as United States assayer. There is a foundry and machine shop here, owned and run by Messrs. Davis & Tatem, where quartz mills, flour and saw mills, hoisting works, etc., are put up in complete order, and also a smelting furnace, at present run by Mr. V. T. Preest, known as the Helena reduction works, and supplied mostly by the galena and carbonate ores of Lewis and Clarke county, or from the Rumley, the North Pacific and Molly McGregor mines of Jefferson county. The furnace has four stacks, intended to be run two at a time, alternately, and is fitted out with a 60-horse engine and boiler, Roof's blower, Dodd's rock-breaker, a three-stamp battery, two cupel furnaces, improved wrought iron tuyeres, assay office, and a complete set of implements, together with a house sufficiently large to shelter 20,000 bushels of coal.

In this connection may be mentioned a new and improved mode of

Marking Minerals, Ores,

Fossils, petrifications and other specimens for cabinets, an invention of Mr. Chas. W. Cannon, of Helena, and covered by United States patent. The improvement consists chiefly in the use of plaster of paris, or a cement formed in the main of this material.

A small-pointed brush is used for putting on the inscription after the cement has become set, using India ink or paint. If preferred, the entire surface may first be covered with ink or paint, and the letters put on by scraping off the ink with some pointed instrument. In one case the letters will be black, and in the other white, each on a different colored background.

The labels can be made to assume any size or shape to please the fancy, and are not liable to injury, however roughly handled, so perfect is the adherence of the cement to the ores. The cabinets of Montana are generally marked in this way, and where neatly executed, the labeling presents a pleasing effect and seems to give universal satisfaction.

The annual bullion product of the Territory is estimated at about \$4,000,000. About \$500,000 of this is purchased at Helena, the product of the placer and quartz mines of the immediate vicinity and districts more or less remote.

The Gravel Mines

Were at one time very productive, and are still yielding considerable amounts. Those of Last Chance—the principal gulch—have yielded steadily and in large amounts since 1864, the total product to date probably not falling short of \$12,000,000. Grizzly gulch, from the Park down, has paid well the past season, most of the claims running from \$5 to \$7 per day to the man, and one claim at least has paid in dividends about \$1,000. Dry gulch and its tributaries panned out at the rate of from \$5 to \$10 per day, saying nothing of the Oro Fino, Tucker, Holmes, Greenhorn and other gulches. Immediately below Helena there is a heavy deposit of gravel, that has paid exceedingly well, and is still quite extensive. It appears to be an older channel that once ran at right angles to the present gulch, with a depth of pay dirt averaging 35 feet.

About \$1,000,000 have been taken out here by three companies. Mr. Frank Taylor's claim of 13 acres is one of the most valuable, and has hitherto been worked by means of towers 60 feet above the surface, into which the gravel is hauled on tramways by machinery, and thence dumped into sluice boxes. In this way, as much as \$154,000 were taken from a space 135 by 130 feet. This claim and others here will soon be worked to much better advantage when a

Large Flume,

Three feet wide by three deep, reaches this fine body of ground. It will be completed by Mr. W. A. Chessman at a cost of \$10,000, and has already been extended about a mile. It is intended not only for the working of a large body of gravel belonging to this gentleman, who also owns the water and expects to make it personally profitable, but also for the benefit of all owning claims in this locality.

As much of this ground has paid from \$5 to \$20 per day, with some runs as high as \$50 and \$100, a good return may be reasonably anticipated on the completion of this enterprise.

Quartz Mines Around Helena

In some respects one of the most remarkable mines ever met with, and quite a curiosity in its way, was found in this vicinity. It is won-

derful in the richness of some of its ores, as well as in their variety and combinations, embracing, as the details will show, every different class of silver ores known to the mineralogist if not some not laid down in the books.

The Lexington, belonging to Messrs. Benjamin and Cassel of your city, and Mr. W. C. Childs, agent of Wells, Fargo & Co., Helena, occurs in a granite formation, giving every evidence of a true fissure vein, with dip regular and well defined walls.

The width of vein matter is about five feet, the richest ore being from four inches to two and one-half feet thick, although not uninterruptedly continuous. The greatest depth at present attained is 80 feet, with a level of about 20 feet. Three men have extracted the past season 150 tons of ore, 135 of which was fair grade milling—55 tons yielding \$103 in silver. The other 15 tons consist of extremely rich ore, the silver appearing in every imaginable chemical combination, and the assays made from the ore from time to time, as taken from the mine, running (many of them) high into the thousands.

Pieces of horn silver from one to three pounds have occasionally made their appearance, showing a value by assay of upwards of \$24,000. Besides this, wire silver is sometimes found that is a curiosity in itself worth seeing. The wires are from the size of pins to that of ten-penny nails. About 300 pounds of the wire silver have been mined, the pieces weighing from 2 to 30 pounds each, and literally permeated with the coarse wires, which may be seen projecting out from all points of the ore.

The assays of this class show a near approach to pure silver, running in the neighborhood of \$35,000.

At the bottom of the shaft where they are at work (80 feet from surface) there is a vein from 12 to 18 inches in width, with ore in considerable quantities, containing black sulphurets of silver, horn silver, generally diffused through the ore, copper, silver glance, honey-combed chloride ore and virgin (leaf) silver. At this point the walls are perfectly defined and the vein on both incased between seams of talc, the ore assaying from \$12,000 to \$24,000.

By digging along the surface for 300 feet, in addition to the classes of ore already named, they have obtained copper glance, arsenic silver, and brittle silver ore (stephanite), white quartz carrying silver in chlorides, argentiferous galena, porous chloride ore, carbonates of lead intermingled with black sulphurets of silver, and other varieties or combinations either new or unknown to two or three mining engineers from New York who examined the mine and pronounced the productions the most extraordinary they had ever seen. One specimen weighing 37 pounds was seen here, perhaps fully one-fourth of horn silver.

A number of fine specimens may be found at the office of Cassel Brothers, in your city.

The Silver Hee's,

A recent discovery, owned by Messrs. Davis & Corwin, is situated on the side of a steep mountain a short distance above Helena, where it can be opened to great advantage by tunnel. The country rock is limestone, but adjacent to the slate. The crevice is three feet, with an average ore vein of argentiferous galena of 12 inches—running 40 per cent. lead and \$50 per ton silver. It is promising for the amount of development, and it is hoped that it may widen to a large chamber, as is often the case in similar formations.

Mr. J. Schafer, a little below Unionville and about four miles above Helena, was making good wages on the McIntyre lode. Its direction is east and west through the granite, not far from the limestone, and is from six inches to two feet in width. His rock is worked by arastra, on which he has made some improvement for facilitating crushing which cannot now be made public, as it has not yet been patented.

The National mining and exploring company, once known as the Whitlatch Union, is in possession of a property that has yielded not less than \$2,250,000, but at present depth of incline, 950 feet, find their vein broken up and faulted by a cross lode. With the exception of some \$20,000 taken out the past season on the tribute system, near the surface or from float quartz, but little has been done.

New machinery, consisting of a Babcock and a Wilcox sectional boiler and a large Worthington duplex pressure pump, were put up last fall and the mine was pretty well drained when visited. Some ore was reported in sight, and a further persistent search for the vein was in contemplation.

The Columbia, on the Park lode, five miles from Helena, had just resumed work with new machinery. They have shipped during the past four years over \$750,000 in bullion. At the depth of 300 feet their ore vein is three feet and runs from \$15 to \$18 in gold. The Evelyn, adjoining, owned by M. Courtwright & Co., had paid from \$20 to \$50, but no ore was being crushed.

The Pedro,

On the same lode, and a mile from Unionville, had reached a depth of 120 feet; vein from six inches to 18 inches, in granite. The quartz works from \$25 to \$75 in gold; the last lot, which was being cleaned up at Harvey's mill, in charge of Mr. J. W. Dalrymple, brought the company \$40. In accordance with a statement made by Mr. Henry Richards, the superintendent, and also a stockholder, it has paid its regular dividends since the 1st of last May, when the work commenced. With proper facilities

for mining and crushing \$10 gold quartz can be made to pay on this lode if the vein continues to hold its usual width.

The North and South Pacific, on Red mountain, in Ten-mile district, is well opened by tunnel and shaft. Lode from 25 to 30 feet, much of the ore consisting of antimonial silver. The shipments average from \$230 to \$300 per ton.

On the same mountain range, 15 miles from Helena, Mr. C. B. Vaughan is sole proprietor of

The Little Jennie,

On which some work was done in 1873. Two lodes cross each other at this point, with ledge matter in places from 40 to 50 feet wide, where they are reached by tunnel. Levels have been run on one of these, known as the Peerless, 140 and 340 feet east and west, and another, on the Little Jennie, 200 feet, disclosing four rich chimneys of argentiferous galena and gray copper ore (fahlerz). The fahl ore gives assays all the way from \$240 to \$18,000. First-class shipped to Freiberg worked from \$700 to \$900 per ton, and one lot sent to San Francisco yielded \$1,000; second class worth from \$250 to \$400. The lode is encased in granite walls, containing streaks of porphyry and talc mixed with veins of milling quartz, and widening in portions of the mine to chimneys of nearly pure ore, stamping it with a character for richness rarely surpassed, and ranking it among the best paying mines of Montana. A. C. K.

Helena, M. T.

Santa Cruz Water Works.

EDITORS PRESS:—The new water works at Santa Cruz is one of the finest and most valuable improvements connected with its rapid growth, and will be largely promotive of the future health and comfort of this little seaside city. These works have been built by a corporate company, whose president is H. K. Moore, Esq., of San Francisco, where is also its business location. The resident superintendent and manager of the works is E. R. Morgan, Esq., to whose business tact and constructive skill the company is largely indebted for its success in the completion and proper working of this great enterprise. In attempting to report these works for the information of your readers, your correspondent would claim no especial reportorial acumen by pretending the acquisition of an item either unknown to common observation, or unheralded to the world. For these works, sitting upon the high hillside like a large fortification, above and overlooking the town and adjacent country, are the most conspicuous objects seen in approaching the city from any direction; and they have been duly noticed, from time to time, by the local journals, in their progress and completion. But it is to give a larger play to our warm individual interest in whatever enhances the interests of our former home, and to bear testimony to the public value of the conception, to the wisdom of the investment of capital employed, and to the skill displayed in the construction of these works, that we attempt these notes.

Calling at the office of the company on Pacific avenue, near the postoffice, we were invited to take a seat in the buggy of the superintendent, and were taken to the

Two Reservoirs

On the hill, at the point where the bluffs, which form the back wall of the first terrace of the upper town, bend abruptly to the left and form the western boundary of the San Lorenzo valley. Then extending northward a mile or more, these bluffs rise up into the mountains which run the whole length of the Lorenzo river. The location of these reservoirs not only secures the proper elevation to carry the water with a heavy pressure to all parts of the town and the country for miles around, but also affords a magnificent view of the entire region in every direction.

The company have secured four acres of ground at this point, beginning on High street, with a frontage of 150 feet or more, and running back in a northerly direction to near the top of the bluff at its upper corner. The surface is covered with soil, and under it a chalk rock formation of unknown depth. The ground for about half its length from the street has but a slight declination south towards the street and east towards the river. From this middle point the excavations begin, which divide the other portion into two ascending terraces. The lower boundaries of these terraces are retreating walls made of the stone taken from the excavated hill. The lines of these walls are not straight, but slightly curved, so as to pass around the hill and at the same time give a graceful contour to the ornamentation of the grounds, which it is proposed so to beautify that they will afford the most delightful place of public resort to be found near the city. The lower reservoir is located at the lower end of the terrace, nearly midway of the grounds, and is a parallelogram 60x80 feet, sunk into the rocky foundation 11 or more feet, its almost perpendicular walls water-cemented, and holding 300,000 gallons of water. It is enclosed with a high board wall, neatly white-washed, and leaves a walk four feet wide all around the reservoir on its inside. The upper and highest reservoir is at the highest and extreme point of the bluff, at the upper end of the terrace, and has a view of the San Lorenzo valley northward. The view then swinging to the right, through

all intermediate points of the circle, looks the whole length of the peninsula formed by the river and ocean, and far out upon the latter, to the extreme southwest. This reservoir, like the other, is sunk into the solid rock; but, unlike the other, is an elliptical bowl in shape. It is likewise cemented, enclosed and holds about 150,000 gallons. The enclosures have windows in their sides to afford an unobstructed view of their entire interiors to an interested and curious public. Both reservoirs are well stocked with fish to keep pure the water, and will afford rare sport to the privileged angler.

The lower reservoir is 90 feet and the higher 150 feet above the river, where the

Steam Pumps,

Enticing the unwary waters into their monstrous throats, force them along and up their dark tubes to these lofty receptacles, 4,700 feet away.

Automatic Arrangements.

Both of these reservoirs are furnished with a metallic float, which is so ingeniously contrived that it automatically by two levers (one for each reservoir), surmounted at their outer ends by a broad, square, white tin, intended to be seen from a distance, and so attached to an elevated pole fixed in the wall of the highest reservoir that they fall outwardly, through all the intermediate points of the quadrant, from a perpendicular to a level position, indicates the exact depth of the water in each reservoir. By this simple mechanical contrivance a telegraph is constructed which informs the engineer near a mile away when his pumps need to begin or cease their motion. But this is not all that this float does, for when the lower reservoir is filled (and this reservoir is always filled before the upper one) the float reaches and loosens a spring which by its recoil opens a valve situated in a small pipe coming from the upper reservoir and terminating in a little house located over the spot where the feeding main branches, one leading to the lower and the other to the upper reservoir. This valve opens over a little water-wheel, which by its connection with proper machinery closes the valve of the lower branch main and opens the valve of the upper branch main, thus stopping the water flowing into the lower and forcing it an additional height of 60 feet into the upper reservoir. When this reservoir in turn is full, its own float by the same contrivance reverses all these movements, closes the upper pipe and again opens the lower. Thus, by this automatic telegraph and valve-controlling arrangement, the reservoirs are regulated, never lacking water and never overflowing.

The Engine House

And pumps are located on the San Lorenzo river, about a mile above Santa Cruz. The boiler-house is 20x30 feet, contains the largest boiler in the country, is very complete, and is furnished with patent safety valve and whistle. The pump room is 18x25 feet, two stories; the upper story occupied by engineer and family. The buildings are well built, hard finished and tastefully painted, and, notwithstanding the throbbing of its huge pumps, all has an air of quiet neatness. The pumps are Hooker's patent, manufactured and put in place by W. T. Garratt, of San Francisco; they are two in number, and are a marvel of compact efficiency. The larger one is a strong iron box three feet ten inches long, one foot eight inches in thickness and two feet deep, and contains within its recess 20 valves and other machinery, besides 35,000 gallons of water per hour, which, passing through it, it forces along the eight-inch feeding main with a pressure of over fifty pounds to the inch. The engine which drives this pump is as simple and concealed in machinery as the pump itself; for all that can be seen is a cylinder 18x24 inches at one end of the pump box and two feet from it, with a piston traversing between, with both ends hid within the cylinder and the pump box respectively—the steam power required to produce this simple motion rising to the pressure of 75 or 80 pounds to the square inch. This simple apparatus, with a few steam pipes and water pipes leading to and from the pump, is all that can be seen of that mighty force which propels 35,000 gallons of water one mile (nearly) and into the air 150 feet every hour! There is a smaller pump like the larger which can be worked, and the combined capacity reaches 50,000 per hour. The water supply is drawn from an immense walled well, just outside the buildings, entirely protected from possible overflow of the river. This well is sunk several feet below the river bed and forty feet at least from it. Its water sinks through immense sand filters laid in the bottom of the river, and passes into it pure and limpid by the force of gravity alone.

The feed pipes, as well as all the mains through the city, are the

"Wyckoff Wooden Pipe,"

And will bear the pressure of 900 pounds to the square inch. This supply pipe and the mains into the lower town are eight inches in the clear. The mains into the upper town are six inches. Branch pipes from four to six inches, and short runs are three inches. The mains, with all their branches now laid, reach the distance of 8½ miles. The company has made up to the present 200 connections and expect to make during the coming year 400 more. The revenue already derived from this source amounts to one per cent. on the investment. Pretty well for the first year's work. The company will soon run their mains along Mission

MECHANICAL PROGRESS.

Rules for Tempering Steel.

The *Iron Age* gives some rules to be observed in tempering. 1. The steel should be very hard before tempering. If the articles to be tempered are not properly hardened at first it will be time and labor lost to temper them. 2. The heat for tempering should not be too suddenly applied. The slower the heating the tougher and stronger the steel. 3. The most careful and experienced workman is liable to be deceived in the color of the steel, and consequently in the temperature in imperfect light or at twilight. 4. Where water is used for plunging the steel in, the less frequently it is changed the better, provided it does not get greasy. The temperature to which the steel should be raised for various purposes is shown by the color of the steel when heated. Lancets, which must be very hard, in order that they may be ground to a keen edge, are tempered to the faint yellow tinge, equal to 430° F., while razors and surgical knives, which must be less easily broken, are tempered to the straw yellow, equal to 450° F. Pen knives are tempered upon an iron plate over the fire, the blades being laid upon it on their backs until they have acquired the full yellow color, equal to 470° F. Cold chisels and large shears for cutting iron, must stand rougher usage, and are therefore tempered to a brown yellow, equal to 490° F., while the brown, with purple spots, equal to 510° F., marks the tempering heat for axes and plane irons. Table knives are heated till they acquire a purple color, equal to 530° F., in order to let them down to the proper temper, and articles in which great elasticity is required, such as swords and watch springs, are tempered to a bright blue, equal to 550° F., while saws are brought to the highest tempering heat at which the dark blue color shows itself. This temperature, about 600° F., is that at which oil boils and flames, so that a bath of oil is very frequently used in tempering, the articles being immersed in it and the temperature ascertained either by a thermometer, or by the volume and color of the smoke which rises from the oil. Some tools are annealed by plunging them into oil heated to 400° F., and allowing them to cool down in it. Small steel tools, after being hardened by chilling in water, are coated with tallow heated over a flame till the tallow begins to smoke, and then stuck into cold tallow. Large steel implements are let down to the proper temper by being heated in a kind of oven known as a muffle.

A Note on Files.

Prof. J. E. Sweet, of Cornell University mechanical school, in one of his recent lectures, gave his students the following note on files, as reported in the *Polytechnic*: Each file should have a well-fitted handle; and for a given purpose I know of nothing more utterly unsuited than the tangs or shanks of files as universally made. By remodeling the tangs of our entire lot of files, I hope, during the term, to show and convince you that there is a good form as well as a bad one; although I feel sure that a quarter of a century at least will be required, (our graduates holding prominent position) before a general move can be made to change the wrong for the right. As they are now made, they are expensive to forge by hand, and very difficult to forge by machinery. There is no tool by which a proper hole can be made in the handle; nor can there, while they are of all sizes and degrees of taper, be such a tool made. Besides, the tangs will not, even if put in in the best manner, stay in the handle as they should. There is no more sense or economy in changing a file handle every time one wants to change a file, than there would be in so changing a hammer handle; and if the tangs were of such form that when a handle was put on it would stay, workmen would no more think of shifting the one than changing the other. That the part of the tang next the file where the handle is protected by the ferule, should be tapering to give it strength, is all right; but that the part back of the ferule should be parallel, or nearly so, and of such size that it will drive tightly within a standard sized hole, is in my opinion the true form. The handle, to be used a long time without cramping the hand, should have a good deal of convex surface and very little, if any, of concave; and there should be no beads or ornaments. The wood from which they are made should be thoroughly seasoned, or the ferules threaded on as a nut is screwed upon a bolt. Gas pipe, threaded on the inside and cut into short lengths, makes durable ferules. Files are cut their whole length, and to use only a small portion in the center sacrifices half their value. The best practice is to run their entire length at each stroke, running them at a steady uniform speed—not too fast; and to exert sufficient pressure to make them cut from end to end. If a file is run too fast, or allowed to slip over, it wears away the teeth; a pretty well worn file will cut if held to the work with sufficient pressure; and for steel (unless the file is made specially for it, with obtuse teeth), it will endure more if used first on softer metal. The teeth of a new file are rapidly broken off, unless used with care.

Welding.

We recently printed a paragraph on welding as viewed by an English mechanic. We read that this statement has called up some controversy. At a recent meeting of the Foremen's Association, Mr. George Newcombe made a 'dead set' against certain opinions which had been expressed on the subject at various discussions of the Iron and Steel Institute. He considered that they were quite mistaken as to the conditions necessary to secure good welding, from an erroneous notion of what was actually done, or sought to be done. He maintained that the sand was only necessary as a refractory agent to prevent the conduction of the heat, and had no use whatever as a means of cementing the pieces of iron under the process of welding. Mr. Howson defended his opinion by asserting that the melted silicate promoted welding by preventing oxide forming on the metal and so barring the way to an intimate homogeneous weld. It turned out, however, that each was looking at the matter too exclusively from his own peculiar standpoint. Mr. Newcombe arguing as a smith, and Mr. Howson as a manufacturer; for the slag undoubtedly is necessary for protection in puddling. Mr. Head, as usual, made a dash at first principles, and considered the reason of the matter lay in the answer to the question, What is welding? Probably they would never arrive at a solution of the nature of this particular form of the cohesive power of attraction. All they were likely to be successful in was in finding out the proper conditions. It was a question they were all deeply interested in, and very much worth studying. The permeation of hot iron by carbonic oxide and carbonic acid was also discussed with reference to the blisters in plate iron so annoying to manufacturers, some suggesting that they were formed by carbonic oxide, intercepted by the rolled skin, and others that they were caused by the generation of carbonic acid, the balance of opinion being in favor of their being 'bottled-up' beads of carbonic oxide. Towards the conclusion, an ironmaster present made the very wise remark that the masters might very often be benefited by taking a lesson from their workmen.

New Way of Making Miners' Picks.

An Englishman has devised an improvement in the manufacture of miners' picks which is thus described: In the first place a rod, bar or plate, consisting internally of steel, and externally of iron, is formed by making a pile, and rolling or drawing down the pile into rods, bars, or plates, of the section required, having the inner core of steel embraced, as it were, by a wrapper of iron. For such tools as miners' picks a compound bar of the above description is made, and cut into the lengths required for each tool; one or both ends of each length are afterwards sheared, cut or forged, or otherwise drawn down or shaped to a point or working edge or face, which is then hardened or tempered. The bar at mid-length or elsewhere may be split longitudinally and opened out to allow of its being attached to a handle, or other means of attaching it to a handle may be adopted. Picks constructed in the manner above described may be made lighter and stiffer than picks constructed in the ordinary manner, and will, in addition, when a cast-steel core is used, possess the principal advantages of picks formed entirely of cast-steel, without the disadvantages which sometimes tell against the use of such tools. The steel will also be protected in manufacture, and also when the ends of the pick are reheated at the time of dressing or sharpening in the ordinary way. If by repeated sharpening the iron be found to overrun the point of extremity, some of the iron may be removed by paring or otherwise, and the extremity may be upset to facilitate doing so.

MAKE YOUR INVENTIONS KNOWN.—Inventors and others having new machinery and implements to describe, should have cuts of them made. The *Newark Advertiser*, speaking of this matter, says: "It is hardly possible to introduce successfully an improvement in machinery of any class without the aid of a good engraving. It not only serves to show at a glance the valuable features of the machine, more effectually than the longest verbal description can do, but it also constitutes the very best method of advertising an invention, its attractive appearance securing the attention of the reader, while a column of reading matter might be overlooked." All of which is true, and cannot be too strongly impressed upon the minds of those who have new mechanical inventions which they wish to introduce to the public.

NEW RAILWAY CARRIAGE.—A French company is now building a special type of carriage for service on the little railway between Bayonne and Biarritz. The designer is M. Carmanraud. The framework is entirely in iron; in spite of their large size the weight of the carriages is relatively small; the panels of the body are made of thin slips of wood, covered on both sides with varnished canvas. There is a covered upper story and an interior staircase; each carriage is arranged for three classes, and has a goods department and smoking platform as well. The open spaces are as large as possible, to permit good views being taken. Petroleum is used for lighting; the lamps are so arranged as to give light to the interior and at the same time show the signals. Each carriage, all full, accommodates ninety-two passengers.

SCIENTIFIC PROGRESS.

Caterpillars in Coal.

At the last ordinary meeting of the Derby Naturalists' Society, the *Colliery Guardian* says that Mr. A. H. Stokes produced a caterpillar which had been presented to him as a 'find' in the coal, 61 yards deep, at High Moor, Eekington. The man from whom he obtained it stated that, on splitting a piece of coal in the ordinary course of his labor, he discovered the insect curled up inside, and it being of a 'blood-red color' it so alarmed him and others that, at first, they did not dare touch it. Eventually it was secured and taken to the daylight, where it proved its mortality by devouring voraciously some leaves. Although the spirit in which the insect had been preserved had tampered very much with the delicate epidermis, and had thus destroyed the coloring, yet it was soon recognized as the larva of the goat moth (*Cossus ligniparida*), the larva of which is supposed to be the 'cossus' of the ancient Romans, by whom it was esteemed a great table delicacy. The insect appeared to be 'full fed,' and quite ready to form its cocoon, and this would account for the position in which it was found. How it came down the mine it is, of course, impossible to say. The ordinary home of the insect is in the wood of willow trees, where the pupae are sometimes found, and it may have descended in the timber used in the mine, or it may have descended unobserved on some of the men's clothing. Some persons might doubt the ability of an insect to eat its way into coal. On this point, fortunately, we have ample evidence. A gentleman once placed some of these larvae in a box, which he deposited upon the piano. He was rather surprised the next morning on finding that these industrious biters had gnawed their way through the box into the piano, and had evidently gone on a voyage of discovery into the interior. Prof. Henslow, writing to the *Zoologist* (vol. viii., p. 2,897,) says: "I placed half a dozen caterpillars of the goat moth in a glass jar, with sawdust and a piece of willow, and covered the mouth with sheet lead, which was perforated with an awl to admit the air. Three of the caterpillars were to-day crawling on the floor, and on examining the jar, I found that they had effected their escape by gnawing the lead, having enlarged two of the perforations sufficiently to enable them to pass out of their prison." Now, an insect which can eat its way through lead and through walnut wood would not make a difficulty over a piece of coal. The larvae of different species of *Dieranura* are similarly powerful in the jaw, and Mr. Stokes's insect was at first taken for one of this order.

Spectra of the Planets.

Some researches by M. Vogel on the spectra of planets, undertaken in view of a prize question proposed by the Copenhagen Academy in 1873, which gained the prize, have been published in *Poggendorff's Annalen*. The following is a short resume of them: The spectroscopic shows the light of the planets to be in general reflected solar light. The principal Fraunhofer lines are found in the light of the brightest. The idea of a light proper to Jupiter and Saturn, as explaining their peculiar whiteness, seems unfounded; for the presence in the spectra of these planets of lines and bands of absorption, identical with those produced by our atmosphere, seems to prove the existence of aqueous vapors in the gaseous envelopes of these planets, and it is difficult to suppose the temperature of their surface high enough to cause an emission of light. The solar and planetary spectra differs in that the latter have absorption bands, more or less intense, in the less refrangible parts; and these may be attributed to the atmospheres of the planets. The further the star is from the sun, the more preponderating is the influence of this atmosphere. The interior planets, Mercury and Venus, have only very weak absorption bands in the red and yellow, which are coincident with lines produced by passage of light through our atmosphere. Mars presents the same bands, but more marked. In the spectra of Jupiter and Saturn, there is, besides these bands, a very intense band in the red, and all the more refrangible part (violet and blue) is greatly weakened, without bands being distinguishable. Lastly, the spectra of Uranus and Neptune are crossed everywhere with broad and intense absorption bands.

MURDER OF SCIENTISTS.—The *Chicago Times* says: Late news from New Guinea conveys the intelligence that two persons engaged in making scientific collections on that island were lately murdered by the natives. The one was a Dr. James of the United States, the other a Swede, his companion, who had been some time with him exploring Gule island. The two had gone in their large boat to the east side of Hall sound to shoot birds of paradise, when they were attacked by three canoes and both were killed. The native crew managed to get away in the boat and carried the news of the sad calamity to Cape York. Only a fortnight before the notice of his death reached England Dr. James's first collections arrived there, and the excellent way in which they were preserved, together with the careful notes accompanying them, betoken that science has lost a promising auxiliary through his untimely decease.

The Moon's Motion.

The reduction of the star occultations observed at the transit of Venus stations, for the purpose of determining their longitude, renders necessary an investigation of the errors of the moon's place, as given in the Nautical Almanac for the period during which the work was in progress. Such an investigation, says the *Independent*, has just been published by Professor Newcomb, as Part III of the papers issued by the Transit of Venus Commission. It appears, in the first place, that, on the whole, the moon has for the last 14 or 15 years been falling continually behind the place indicated by the tables. In 1864 the tabular and observed positions were sensibly accordant; but in 1874 the moon was on the average .94" (about 11 miles) behind computation. In respect to this Professor Newcomb remarks: "The sudden alteration of nearly one second per annum in the mean motion of the moon seems to me one of the most extraordinary of astronomical phenomena; but as I have discussed it in several papers during the last five years, I shall do no more here than call attention to its continuance, and to the impossibility of representing it by any small number of periodic terms, without introducing discordances into the longitude during previous years." The explanation suggested in the papers referred to is that there may have been an actual change in the rapidity of the earth's rotation, the length of the day having recently shortened something like 1-400 of a second, in consequence, probably, of some geological movement of the crust of the earth. Another result, hardly less startling to mathematical astronomers, is the discovery of a new inequality in the moon's motion, amounting to about 1.5" each way. It may be either an inequality of the eccentricity and perigee with a period of 16½ years, or merely of the moon's longitude with a period of 27.4 days. No theoretical explanation of this irregularity has been reached. According to Prof. N., the only apparent cause to which it can be attributed is the attraction of some of the planets. The whole discussion is thoroughly worked out and the paper is one of great interest and importance to astronomers.

Cause of Error in a Thermometer.

Mr. H. C. Russel publishes notes on some remarkable errors in thermometers recorded at Sydney observatory, 1876. For upwards of five years the same hygrometer has been in use at the observatory. The dry bulb is small, only 0.3 inches in diameter, and the instrument, up to February 26th, had always given very satisfactory readings, tested by those of a standard which hangs only 3 inches from it. The difference in the readings was usually 0.2° to 0.3°. On that day the maximum shade temperature rose to 96.4° about noon; at 3 p. m. the dry bulb and standard read 83.7°, and at 9 p. m. 68.9° and 69°. Next morning they read 69.6° and 69.8°. As this was Sunday, they were not read again until 9 a. m. on the 28th, when the dry bulb read 87.3°, and the standard, 64.9°, showing a difference of 22.4°. It was at once thought that the glass was cracked, and let in the air, but as no crack could be seen, after careful examination, it was determined to continue the reading. The author had always found before that if a thermometer cracks in the bulb the mercury rises till the tube is full, and he expected it would be so in this case though he could see no crack. The result, however, was that the difference steadily decreased, at first at the rate of 1° each day, and in 35 days the difference had fallen to less than 0.5°, or almost to its normal condition. Between April 7th and 17th it rose again, then fell. On the 3d of May, and again on the 7th, sudden rises took place; since then the difference has been diminishing, except a slight rise on May 21st and 22d. When very closely examined with the microscope, a very small piece of colored glass is to be seen in the bulb, as if lead had been reduced by the blowpipe, and on one side of the bulb a mark is visible, as if there was a minute quantity of water between the mercury and the glass at one spot.

CLIMATIC CHANGES IN RUSSIA.—The winters in Russia are becoming colder every year, and the summers hotter, more dry and less fruitful, owing, as is clearly stated by Livingston, to the destruction of the woodlands which formerly abounded in the southern districts. The clearing of these lands has caused such an enormous evaporation, that many once capacious water-courses have become mere swamps or are completely dry. The Dnieper becomes every day more shallow, and its tributaries are no longer worthy of the name of streams. The question of replanting has frequently been agitated, but the dried condition of the earth in many places in Southern Russia makes it a great difficulty. Energetic measures, however, are about being adopted to overcome this difficulty by scientific means.

SIDERAPHTHITE.—This is the name of a new iron amalgam which is composed of 65 parts iron, 23 nickel, 4 tungsten, 5 aluminum, 5 copper. It resists sulphureted hydrogen, is not attacked by vegetable acids, and only slightly by mineral acids. It is really more useful than standard silver, which it can be produced at a cost not exceeding that of German silver. For alloys which have to be silver-plated to prevent oxidation, the inoxidizable iron, as the above is called, is stated to be a perfectly successful substitute.

The year just closed has been about as bad as any one for stock dealers as they ever had. Although the production has been greater, and the mines have been profitably worked, a general distrust of stock dealing has been manifest, and the public has not come forward so readily as in former years. Again some of the big deals have

The Mining Share Market

The year just closed has been about as bad a one for stock dealers as they ever had. Although the production has been greater, and the mines have been profitably worked, a general distrust of stock dealing has been manifest, and the public has not come forward so readily as in years past. Again, some of the big dealers have left the street and gone into other classes of business, so the market is not so well sustained as usual.

The news from the mines continues good, with the exception that the water on the Comstock still continues to give trouble. The year ends and begins rather darkly for the stock market, but it is to be hoped that this will not have too unfavorable an influence on the mining interests of the coast.

A NEW AUSTRALIAN WILD FRUIT.—MR. W. Toward lately brought under the notice of the Queensland *Chronicle* specimens of a wild fruit which, according to his account, has been only recently discovered by settlers on the Burrum, and of the edible of which even the blacks until lately had no knowledge, they having been first introduced to taste it by observing that their dogs greedily devoured those that had fallen from over-ripeness. In size and appearance it is very like a small apple; the color, externally, bright red; inside, greenish white; the pulp closely resembling that of an apple, but drier and more fibrous. The flavor is tart but not unpleasant, and approximating to that of a common crab or wood apple. It contains five or six seeds of a bright mahogany color, each enclosed in a separate core, and about an inch in length. The tree is described as very tall and ornamental, and the locality where it abounds near the mouth of the Burrum. The fruit, although not very palatable in its wild condition, could no doubt be easily improved by cultivation. The tree in question abounds on the headwaters of Tinana creek and Boppel range, and the apple, by keeping, becomes mellow and delicious. It seems to belong to the sapotaceous order, and to be referable to one of two genera, *Lechros* and *Mimusops*.

THERE are now in operation in the United States no less than 800 paper mills, which are valued at \$40,000,000 of capital invested, with a total production of \$70,000,000. These mills usually employ 20,000 people, whose earnings are footed up at \$10,000,000 annually.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR.

GOVERNOR.—*Amador Ledger*, Dec. 30: About a year ago the stock went begging at about \$1.50 per share, to-day it is worth \$40. This increased value is not owing to the manipulation of stockholders, but the important discoveries which have been made in the mine. The old shaft is down 700 feet. The first level being worked is 500 feet from the surface. Here a ledge is met with five feet thick, and of excellent character of ore. Drifting has been prosecuted on the ledge 140 feet. About the same may be said of the 600-ft level, excepting that drifting has been pushed to 160 feet. In the 700-ft level the ore body averages 10 feet in thickness, and it is the best rock at present met with in the mine. The drift is in 200 feet. This rock is worth \$30 per ton. Taking the rock from the three drifts it is worth \$20 per ton. Three hundred feet north of the old shaft a new shaft is being sunk, 12 feet by 5 feet in the clear. It is down 130 feet and still sinking. For workman's shaft cannot be beaten by any in the county. Drifting is done temporarily with a small engine under large hoisting works can be erected, material for which is already on the ground. The engine is a 16-horse. A 10-stamp mill has been running for about ten months, but the very favorable prospects of the mine have warranted the building of a new 20-stamp mill about eight hundred feet nearer Brydson than the old mill. The new mill is said to be the best in the county. A double track is being run to the mine, the new mill for running in the rock. The length of the track is 1,000 feet. The cars are run with a wire rope, the down going full car hauling up the empty car. In a short time this mine, that was so low down only about a year ago, will be paying its regular monthly dividends.

NORTH GOWER.—*Adjoining* the Governor, the ledge of which has been traced to the southern boundary, the contract was let the other side to sink 200 feet further on the ledge.

BONANZA.—*Belding & Manon*, the owners of the Drytown Bonanza, are in the best of spirits over the development of their mine. The last clean-up paid an average of \$20 per ton—the best yield since the mine has been opened. There is plenty of rock of equally high grade in sight.

CROWN POINT.—The new ten-stamp mill is all ready for work with the exception of laying the pipe for securing a supply of water.

OLIVE.—Is contiguous to the Bonanza on the west. A shaft has been sunk between 50 and 60 feet, giving the richest prospect ever seen in the county. There is no room for doubt concerning the gold-bearing nature of the rock. Free gold and sulphurets are visible all through it.

FRONT.—This is an old mine situated near Drytown. Yesterday it ranked among the richest mines in the county, but from some cause unknown to us work was abandoned.

MONTICLARE.—*Capitalists* from San Francisco were here a few days ago on a visit of inspection to the Monticlar mine. They are thinking of investing in mining property around Jackson. After going over the claim, they expressed themselves as more than satisfied with the prospects of a rich and permanent mine presented to them.

MCHANIC'S MINE.—*Amador Dispatch*, Dec. 30: This mine is gradually becoming recognized as one of the solid and substantial mines of the county as the work of development progresses. The owners have all their machinery in good working order, and are still sinking their shaft as rapidly as possible, and the prospects grow more and more flattering as they go down.

ALPINE.

ADVANCE.—*Alpine Chronicle*, Dec. 23: The drifting is progressing very satisfactorily. Arrangements are being perfected for working the mine on the new level in the spring. The employees of the company have been investing in the stock of the company—showing that they have confidence in the claim.

HAULING ORE.—The continued fine weather is enabling Manager Chalmers to accumulate a large body of Exchange ore at the company's mill, which will soon be completed.

BUTTE.

NEW IDEA IN MINING.—*Butte Record*, Dec. 30: A Mr. Hedges, who, some two months ago, went to Oroville, built a boat 85 feet long and 40 feet wide. A large pipe, which descends through the bottom of the boat, is attached to a derrick and can be hoisted or lowered at pleasure. The idea that caused the building of this vessel is that the pipe can be lowered to the bottom of Feather river, and, by suction, the covering of the bed-rock can be sucked up to the deck, when the gold will be washed out. A similar boat was used at Gold Bluff some years ago, but was not successful. Mr. Hedges feels confident that with the improvements he uses, the boat will be successful. It has already cost him a large amount, but he is steadfast in his faith and has only put in his own money.

CALAVERAS.

BIG CLAN-UP.—*Calaveras Chronicle*, Dec. 30: The extraordinary yield of the Champion mine, at West Point, has been such a regular thing for so long a time that the intelligence of a big clean-up scarcely provokes comment. People have come to regard enormous returns from that mine as a matter of course, and the sight of a posse of armed men conveying a "bonanza" of Champion treasure to town is by no means infrequent. The crushing of 65 tons of Champion ore, just completed, yielded in the neighborhood of \$7,000—an average of over \$100 per ton. And that is not in excess of former returns from the same quantity of rock—not a whit better yield than the mine has been making for years. We have frequently challenged the State to match our "Champion," but West Point still carries the "belt" for having the richest quartz ledge in the county.

EL DORADO.

VOLCANO-INDIAN ITEMS.—*Greenwood Cor. Mount Democrat*, Dec. 30: Business in and around this old mining camp is beginning to wear a look of prosperity once again. I recently visited the place, and found everything in a very promising condition, both in regard to quartz and gravel mines. There are now two quartz mills running there night and day. The mill on the Volcano mine has just lately been completed and put in running order. It is a ten-stamp mill, run by water power, with hardy-gear wheel, and is a complete and substantial structure, with all the latest improvements. The mine and mill are owned by Messrs. Graves, Wolf & Co. The ledge is four and a half feet thick at the surface, and carries its full size down to the depth of 130 feet, where they are now working. They have on the dump about 300 tons of good ore ready for milling. From 17 tons which had been crushed at Georgetown previous to the erection of their own mill, they realized the handsome sum of \$4,000. The other mine and mill (also ten stamps) is owned by a San Francisco company and is under the superintendence of Mr. Rodecker. It is also running full-handed, and with good results. The California water company are making extensive preparations for the opening of their gravel mines, as also are all the miners who own claims in this vicinity.

GRIFITH MINE.—Yesterday we paid a flying visit to the Griffith Consolidated mine, near Diamond Springs. We went to the bottom of the shaft and gave the ledge a thorough inspection. Rich is a feeble word to express the quality of the ore which is exposed. There is fully eight feet of vein matter in sight, a portion of which will yield as much as up in the hundreds, and neither the hanging wall or the foot wall is yet in sight.

FRESNO.

COPPER.—*Fresno Examiner*, Dec. 29: The Ne Plus Ultra copper mining company have nearly gotten their machine in readiness for working. When the mine is started up

again work can be prosecuted with greater vigor and more economically than before. The water will be pumped out and the ore hoisted by steam power. Arrangements are also being perfected for working the low grade ores, of which there is an abundance in the mine. It is certain the mine will pay well when it is again started up.

INYO.

DEFIANCE.—*Consolidated Mining News*, Dec. 30: We are glad to know that the Defiance furnaces are to be started up next Monday, with the fact that Mr. Hedy will start on a routine receiving coal on the 3d of January. He thinks the Centennial year has not been a successful one, so far as mining is concerned, and is bound to steer clear of anything hereafter that is likely to cause or influence a failure on the part of the Defiance. That a most successful run will be made by these furnaces there is not a question of doubt, and as the numerous drifts and shafts now being worked in the mine are all developing good bodies of ore, there is every reason to believe that the Defiance will soon work out of her indebtedness and enter on a prosperous and dividend-paying future. Everything in and around Darwin is now looking more hopeful than ever.

RED ROCK DISTRICT.—The Red Rock mining district is situated about 25 miles from the S. P. R. R. in the Mohave valley. Mr. J. H. Lent has just returned from there. He located several new borax claims, and will return to that district in a few days to enter upon their development. Specimens brought in by him show that the deposits of the borate are nearly in a pure state. This, we understand, is worth in San Francisco \$100 per ton, and it will be even that when shipped to that point for \$17, it can be sold at there a margin for a profit. There is not a question but what these mines will soon attract the attention of capitalists.

WORKING TAILINGS.—A German by the name of Ernest Koch is working the tailings left after ore that has been treated by the chlorination process at the Providence mine. He is a thoroughly scientific man, and is a graduate of the University of Freiberg in Prussia. He has contracted to work 2,000 tons of the material at the Providence and 4,000 tons at the reduction works of Oscar Matham. He has a process discovered by himself, and is enabled to have about 90 per cent. of all the metal left in the pulp. At the Providence he obtains all the way from \$8 to \$15 per ton of silver and from \$1 to \$3 of gold, all of which was formerly thrown away. No silver has been saved at the mine by the mill process. He uses some kind of a chemical that puts all the metal in the pulp into a solution, after which it is precipitated. We were not informed what the chemicals used consist of or how they operate, as the inventor does not wish to give it publicity as yet. We regard Mr. Koch as one of the valuable accessions made to our mining community. He is putting into circulation gold heretofore lost entirely, and which, in its present condition, is of no use to anybody. Gold savers are what are needed now among miners. It is not a question of how much treasure is taken out that determines whether operators will get rich, but how much they save.

LAKE.

ITEMS.—*Lake Democrat*, Dec. 27: The Sulphur Banks quicksilver mining company are putting up new ore driers, in the shape of cylinders which revolve over a furnace while the ore passes through them. The old practice of drying ore in the sun has been found too slow a process. The works under the new regime were started up at mid-day, and the driers are now in full operation. The old Hills mine will put on a full force of hands by the 15th of January. It is expected that the American mine will have 200 men at work by the 1st of January. The Great Eastern Consolidated, John H. Grove, Superintendent, has a new boiler on the ground and is getting ready for work in the spring. The Redington mine shipped 908 sacks of quicksilver to San Francisco during November.

NEVADA.

CRUSHING.—*Foothill Tidings*, Dec. 30: Good crushings are coming from the Alpha & Omega, a claim out by the late owner, Mr. O. H. Mitchell, Capt. Harry Thomas and others. They have been at work on it for several months past, and the rock has paid from \$20 to \$30 per ton right along.

CONSOLIDATED WYOMING.—*Nevada Transcript*, Dec. 30: We were pleased on our visit to the Consolidated Wyoming mine, on Friday, to see 16 stamps pounding away, and to learn from the superintendent that about 500 tons of ore per month is being reduced, which means that the mine are about a dozen miners employed to keep the stamps all going. One miner broke six tons of ore in one day, last week, which fact shows how easily ore is obtained. The sulphurets saved yield about \$80 per ton by the chlorination process. The ledge at the point being worked is from 18 inches to five feet in thickness. We saw the result of a clean-up of the copper plates, while at the same time the rock which was estimated worth \$1,100. Below the plates are blankets and other apparatus for saving gold, which were not cleaned up while we were there. A drift from the lower level was run to the north, 200 feet beyond any place heretofore worked in the mine, and on raising a winze a very rich body of ore has been struck. We saw some pieces which showed gold in liberal quantities. If an extensive body of this ore exists there, the dividends of the Con. Wyoming will be frequent and liberal.

PLACER.

BIG BLAST.—*Dutch Flat Forum*, Dec. 27: We are informed by D. T. Hughes, Superintendent of the Blue Tent Consolidated mines, that a blast of 900 kegs of powder was exploded in the South Yuba claims belonging to that company on Tuesday, which did remarkable execution. There was a straight drift run into the bank a distance of 88 feet, and from the inner end of which drifts were run both ways at right angles a distance of 176 feet. The bank over the drift is about 180 feet high. The explosion of the whole blast was a distance of five or six feet and thoroughly pulverized the whole mass in good shape for working. An eye witness, who is accustomed to such work, says it was the most effective work he ever witnessed. We are informed that the claims of the Blue Tent company continue to look well, in fact never had as flattering prospects as at the present time.

WATER.—The weather continues dry and the supply of water in ditches is still diminishing day by day. The South Yuba canal company turned off on Monday last, having drawn its reservoirs as low as practicable. This of course shuts down all the claims which have been taking water from that ditch. The ditch of the Cedar Creek company has a small head running in it, which is being utilized by the Dyer and Dyer miners. The extensive preparations for a full season's washing, and are anxiously waiting for the clerk of the weather to tap his reservoirs. The Baker claim is the only claim in this section that is washing. This claim is using water about five hours per day, and the work of opening is progressing well. A blast of 80 kegs of powder was exploded on Saturday last, loosening up quite a large body of gravel. The gravel is being washed, and the water is being used. The mines were never in better condition and the chances for a large yield never better. Nearly everything, however, is at a standstill at present, waiting for rain.

LITTLE YORK MINING.—The water was turned on the Empire mine last week and washing resumed. With its heavy banks of blue gravel pulverized by powder blasts, the large boulders by means of derrick, the work is progressing in ship-shape. From the richness of the gravel and the superior manner in which it is being worked, good returns in the future is assured beyond a doubt. The Christmas Hill company are busily engaged in making preparations for washing, which will take one week more to complete.

YOU BET.—Everything is very quiet at You Bet at present, as the water supply has almost ceased. The Hussey claim is fitted up ready to commence washing as soon as water comes. They have just completed a flume five feet wide and 900 feet long. The English company still continue washing a few hours each day.

SHADY RUN.—The Wild Yankee have turned their attention to cleaning bedrock at present. The North Ameri-

can company are still advancing their prospect drifts, with the indications increasing for a very extensive claim.

PLUMAS.

MORE BLUE GRAVEL.—*Plumas National*, Dec. 30th: Messrs. Kelly and Hartley have recently commenced a new mining operation on the Middle fork of Feather river, just below Bell's bar. They made a location of ground some time ago, and have now bought the adjoining claims and have ready to start a new mine near the river, as possible, so as to have the required dump grade for sluices, etc. Mr. Kelly has lately been up at the claims, looking up locations for dump-houses, timber-houses, etc. They are satisfied that they have got the blue lead, and we hope their anticipations will be fully realized. They are the owners of the whole of Poplar creek, a splendid privilege, and propose to divert it across the main river, and raise it to a height of 450 feet above the river bed. Their ditch will then be extended down the river as fast as required. The name of the Spring company has been fixed upon.

ITEMS.—Still the weather is clear, cold and frosty. The miners are commencing to look anxiously for storm, for when they depend upon snow water, they are glad to see the ground thoroughly saturated before the deep snows come. The outlook now is for a dry season, but it may come thick and fast by-and-by and make up for lost time. The quartz mills on Wolf creek and near Greenville are "doing their best," and at work on A No. 1 rock. Quartz is better in Plumas than ever, and confidence in this class of mines is steadily increasing. The Maxwell company are progressing nicely with their drift and flume down the river. The heavy rain early in the fall caused them considerable trouble, but they have repaired damages and are still pushing the work ahead.

SANTA CRUZ.

COAL DISCOVERY.—*Watsonville Pajaronian*, Dec. 23: Wm. Strader and others have for several years past been prospecting to find coal in the Santa Cruz range of mountains bounding the Pajaro valley on the north, on the north side of Corralitos creek, two or three miles above Corralitos. Last week a vein six feet in thickness was struck, and large masses of coal were taken out, and two or three hundred pound specimens brought here. The past three days will be long enough to show that the coal is good, and all who have examined the vein think the mother lode of the range has been found, and that coal mining will, ere long, become one of the principal industries of this section. The works are situated on the lumber tract of Ford & Sanborn, who have given every facility for proper investigations. This discovery, should it prove as rich as is now expected by experienced coal miners, is but an introduction to many more discoveries which are sure to follow in the same range, and will encourage the building, within the next year, of a broad gauge railroad to connect with the Southern Pacific at this place.

SIERRA.

SOLD.—*Mountain Messenger*, Dec. 30: H. Scamman has sold the old Williams place on Dugan flat to Chinamen, and it will be mined away. G. W. Hughes has sold his place to the same company. Said company is putting up a flume to take water from the South Fork.

THE PERFORMANCE of the B. M. locomotive demonstrates that its powers to get out gravel are almost unlimited. From what it has already done it is judged to be capable of taking out 2,000 car-loads in 24 hours.

THE GOLD BLUFF MILL has been running lately and the rock has yielded well.

THE SWALLOW mine at Monte Cristo is paying very well at present.

THE INDEPENDENCE mine has fallen into the hands of the Sierra Buttes company. We are informed that they got the property for about \$15,000.

MINING WORKS BURNED.—On Sunday, Dec. 17th, the works of the North America mining company, at Hesperia, were destroyed by fire. The alarm was given at once, and a brake-pump was manned, but to their consternation they found that the waste-gate of the reservoir was open and no time was to be had. The reservoir was full of water and the flames, which were burning in the mine, soon subdued the flames, the men in the mine were rung out as soon as possible, and fortunately no lives were lost. All the buildings around the mine were destroyed, together with the winter supply of timbers, lumber, hay, etc. The fire burned back into the tunnel as far as the double track extends, about 200 feet, caving in the tunnel and almost utterly destroying it. Ten cars were burned on the track, and five or six more were damaged. The dump and ruined. The loss is about \$20,000 in round numbers.

Nevada.

WASHOE DISTRICT.

CONSOLIDATED VIRGINIA.—*Gold Hill News*, Dec. 27: Daily yield, 275 tons of ore, which is being crushed as fast as it is extracted. The greater portion of this ore is hoisted through the Ophir shaft, as the use of the Consolidated shaft is nearly taken up with the hoisting of ore for the California. Nothing is being done in the way of prospecting on the 1550-ft level. The north winze has been put in good repair, and a drift started south at the 1650-ft level. This drift will be run to a point opposite where the west drift from the C. & C. shaft will strike the ledge, when a cross-cut will then be run to meet and connect with that drift. The face of this drift, from the time it was started, until to-day, has been in ore which will yield \$10 to \$15 per ton. What the width of the ore at this point cannot of course yet be determined, but all doubts as to the ore extending downward is set at rest by the opening of this station.

IMPERIAL CONSOLIDATED.—The sump of the main incline is being cleaned out, and a large water tank is being erected at the 2000-ft station preparatory to resuming the sinking of the main incline. The east cross-cut on the 2,000-ft level is steadily advancing the face showing some fine quartz. The ore vein at that point appears to have a very great width and the developments show that it has not, to say the most, been more than partially prospected.

OVERMAN.—A strong flow of water was encountered day before yesterday in the drift on the 1400-ft level, which obliged a suspension of the work at that point until the large pumps can be put fairly to work. As soon as the water can be drained off winzes can be started downward on the ore from the 1200-ft level.

CALIFORNIA.—Daily yield, 550 tons of ore. The ore stops and breasts in every portion of the mine are showing richly and promise a long and prosperous yield. The south drift on the 1600-ft level is still advancing, the face rich ore. The north winze, which is 1850-ft level from north winze, shows the ore at that point to be as rich as any that has been found on the levels above. This is within a very short distance of the south line, and begins to look as if the opening up of as rich bodies of ore as that has yet been found in the mine was almost an assured fact. The mills are kept steadily running, and the future prospects are, so far as can be judged, are of the brightest character.

NORTH CO. VIRGINIA.—A heavy flow of water and some very soft ground was encountered in the west drift on the 1100-ft level during the first part of the week. The water bursting in from the sides of the drift caused the rock to slake and swell so badly as to oblige a stoppage of the work in the face and the starting of a new drift farther back, in order to avoid the fearfully bad ground encountered.

BALTIMORE AND AMERICAN FLAT.—The upraise on the 1050-ft level is steadily advancing, following the small vein of ore, which continues of a uniform size and character. The northeast drift on the 1450-ft level shows an improvement with every yard that it advances. The west cross-cut from the main south drift on the 1800-ft level continue to improve in both looks and quality daily. The assays are not very large, ranging from \$10 to \$30, but the character of the quartz and ledge is such that there is not a doubt but a concentration of the ore vein has been encountered, which may open into a veritable bonanza at almost any day.

LADY BRYAN.—The foundations for the heavy machinery

are completed. Mr. I. F. Thompson, the chief engineer and contractor, has commenced the placing of the machinery, and will press it to completion at the most vigorous rate possible.

BUCKEYE.—The north drift on the 350-ft level is rapidly approaching the point at which it is expected the best portion of the north ore chimney on that level will be opened. The Hope mill is soon to start up on ore from the mine.

JUSTICE.—Daily yield, 330 tons of ore; mills all kept running to their full capacities. The ore breasts on the 400, 500, and 600-ft levels continue to both look and yield well. The ore stops on the 700 and 800-ft levels are showing a steady improvement. The winze sinking below the 800-ft level is still in ore of a fine quality. The bullion yield is gradually increasing.

BEST AND BELCHER.—Cross-cutting and driving the diamond drills on the 1700-ft level are making fair progress. So far there is nothing of interest in the shape of ore developments.

HALE & NORCROSS.—The pumps were gaining upon the water until the past three days, when a stoppage of the Savage pumping-engine for repairs caused a rise in the water to a point 21 feet above the 1900-ft station, at which point it is now held with the Norcross pumps alone. The heavy head of water is entirely gone, and as soon as the two pumps can again be set at work the flow will be over-combined rapidly.

GOLD & CRYSTAL.—The repairs to the pumping compartment of the shaft are being pushed with all the energy possible. The shaft has not been in as fine working condition for years as it is at the present time.

SILVER HILL.—Sinking the main incline is progressing at the rate of 12 feet per week.

BELCHER.—Daily yield, 75 tons of ore, keeping the Europa mill steadily running. The ore breasts are gradually giving out on the old levels, so that much more of an effort is required to keep up the supply of milling ore than formerly.

CHOLLAR-POTOMI.—Daily yield, 100 tons of ore, the assay value of which is \$30 per ton. Sinking the combination shaft is making good progress.

UTAH.—Sinking the main shaft is making fair progress, the bottom still in very hard blasting rock. The flow of water gives little trouble.

SUCCESS.—The new pumping machinery is in full blast and is doing its work splendidly. Everything works with the utmost ease and perfection, and the water has already been drained almost to the bottom of the shaft.

OPHIR.—Sinking the main incline is making the best of progress. Driving the north drift on the 700-ft level is also making good headway. Daily yield, 200 tons of ore.

FLORIDA.—The flow of water is light and gives no trouble.

ALTA.—It is the intention to send the shaft downward with all the speed possible until the ore vein is reached.

AUREOLA & ARGENTINA.—A drift has been run from the ravine west of the shaft to intersect the bottom of the shaft. This drift will prove a very advantageous arrangement, as it will tap the shaft 100 feet below the surface and save that distance in hoisting or pumping.

LADY WASHINGTON.—The north drift from the main east cross-cut is in 70 feet to depth, following the very promising ore vein or feeder heretofore mentioned. For the last 40 feet this vein has been from two feet in width to the entire width of the drift. It is composed of soft, porous rock, with a mixture of clay, and assays from \$10 to \$40 to the ton.

YELLOW JACK.—Sinking the new shaft is making the best of progress, the bottom in dry ground that works as finely as it is possible for it to do. The side railroad track to the shaft is completed.

LEVATHIAN.—As soon as timbering is completed cross-cutting will be resumed.

PROSPERITY.—Owing to the great amount of water, sinking the shaft deeper is found to be inexpedient at present.

KOSKUTIT.—The cross-cut on the 500-ft level is steadily advancing. The rock begins to show signs of softening, indicative of a near approach to the ledge.

CALDONIA.—Sinking the main shaft is making about two and a half feet per day. The rock in the bottom is not so hard, but the flow of water is still strong.

THE WEST TUNNEL.—The west tunnel, running to the water recently encountered in the bottom of the shaft, will reach a point directly under the shaft in about 10 days' time.

DAYTON.—The north prospecting drift on the 220-ft level is showing some fine ore. Both of the north drifts on the 500 and 700-ft levels are looking splendidly.

TROJAN.—The ore body continues to improve. In the north drift on the 300-ft level. The upraise on the same level is also showing finely.

SAVAGE.—The heavy pumping engine has been delayed in its operations for several days past, on account of having to put a new piston in the large cylinder.

SILVER CITY.—The work of cleaning out and repairing the incline and reopening the lower level has made excellent progress. The engine is now in full work, water reduced, and ore extraction is now in order.

SOUTH COMSTOCK.—The fine quartz vein run into by the main east drift at the 300-ft level continues its good showing and excellent assays.

PHIL SHERIDAN.—The flow of water is not strong and gives but little trouble.

CROWN POINT.—Sinking the main incline is making the best of progress.

TANOR.—Preparations for the erection of the new hoisting works building and machinery is going ahead rapidly.

STRET TUNNEL.—Total length of tunnel, 14,507 feet. Face of header in a hard composite of porphyry, quartz and clay.

BELMONT DISTRICT.

THE STRIKE.—*Reese River Revueille*, Dec. 26: From the numerous private telegrams received by us to-day from Belmont, the inference is that the recent strike in the Belmont mine is a valuable one, and of some importance that is stretched to its full distance. One dispatch, from a very reliable gentleman of Belmont, says that the strike was made in the south drift, on the 530-foot level, west vein. That being the case, the development will prove the most valuable ever made in the mine. We congratulate those who have their all at stake in that good old camp.

ELY DISTRICT.

BULLION.—*Pioche Record*, Dec. 23: Wells, Fargo & Co. shipped bullion yesterday valued at \$1,382.

ORE.—Alfred Grant arrived from Leeds on Wednesday with a lot of ore from one of Barbee's claims. This ore will be crushed at the Alps mill. Ore was traveling down Main street to the Alps mill yesterday in large quantities from the Raymond & Ely mine.

A RUMOR.—We have it on pretty good authority that the Newark mill, in Condon canyon, is about being leased by two well-known business men of Pioche. The aid of that mill would be of immense benefit to chloriders, who now have to wait too long a time.

THE HSA.—All the paraphernalia of the t-b-stamp mill at Hesperia has been removed to Leeds district with the exception of a spur wheel and some battery blocks. The wheel was too large for the small Mormon wagons, and a special contract with some of our teamsters here will have to be made.

EUREKA DISTRICT.

THE RICHMOND.—*Eureka Sentinel*, Dec. 29: This mine is a practical demonstration of the fact that the despised limestone formation of the Base Range contains a deposit of a body of ore second to none in the State outside of the Comstock, and vying with that in its proportions and value. It has not achieved a notoriety commensurate with its deserts, from the fact that it has not been the shuttlecock of the stock board, as it is under the control of an English company, who are content to pocket their dividends without the intervention of the brokers. The mine is worked intelligently and with due regard to the future needs of its increased development. During the last six months a body of ore was found on the lower level that has proved itself a veritable bonanza, its extent and value as yet undetermined. The breasts and stops on the 900-

street one and a half miles to the "Natural Bridge," and another across the San Lorenzo and on the Branciforte terrace, giving to all East Santa Cruz an abundant supply of soft water.

We will close this already lengthy article with the statement of two points which have been attained in the construction of these works in the direction of economy, both in outlay of money and expenditure of mechanical forces, illustrative of wise management and constructive skill by the resident superintendent. The first is the attainment of an equal pressure throughout the length of the mains in the town by means of a uniform and direct grade from the top to the lowest level in the pipe which connects the mains with the reservoir. This gives the full pressure of the altitude of the reservoir (which is from 90 to 80 feet in every part of the city), with but little loss by friction. The other is, by an ingenious device, the transformation of the feed pipe into a returning supply main. This is accomplished by a valve in a pipe connecting the feed pipe with the main descending into the town. When the pumps are working, the pressure of the water flowing through the feed pipe into the reservoir closes this valve, but when they cease, this valve opens and the water flows back in the feed pipe, equally as in the town mains, in proportion to the consumption of its water. C. N. W.

Watsonville, December 18th, 1876.

Quicksilver.

The following exhaustive article on "quicksilver," by Senor Don F. A. Sola, we take from *Iron*: Spain, for several centuries, had exclusive possession of the sources of the supply of quicksilver. The Spanish mines at Almaden, which, in spite of the important discoveries mentioned further on, are the richest deposit in the world, were worked in the most remote periods. A passage of Pliny shows that the Romans depended on them exclusively for the manufacture of vermilion, and he gives evidence of their immense importance in the ancient world. When the 10,000 *libre* of ore had been extracted from them for the needs of the year, they were shut with solemn ceremonies, and the key of the mines was lodged with the prefect. They could not be opened again without orders direct from Rome. It is generally considered that the Carthaginians, or at least the Phenicians, preceded the Romans in working the Almaden mines. Historic proof of this fact, it is true, is wanting, but its admissibility seems to me to be possible; firstly, from the great importance attached to their Spanish possessions and their mineral wealth by the Phenicians; secondly, from the proximity of these mines to the center of the Phenician occupation in Spain; thirdly, from the manufacture of vermilion denoting a certain degree of progress in industrial arts, which is more intelligible on the part of a commercial people than on the part of a mere nation of soldiers; fourthly, from the fact that the Romans, who never displayed any marked aptitude for industry, were but the pupils of the peoples who had preceded them in civilization.

Whatever their antecedents, the Almaden mines stood alone in the world during the long period between the rise of the Roman power and the beginning of mineral industry in America.

The separation of silver from its ores, in the amalgamation process, is the principal large use to which mercury is put. The discovery by Spain of the rich silver mines of Mexico and Peru caused a great increase in production, and from that time forward Almaden became important. In Peru the cinnabar mines of Huancavelica had been discovered, and in Austria those of Idria, in the province of Carniola; but the former were closed at the end of the last century, the winning having been conducted in a very reckless fashion. The Spanish government, which retained a monopoly of the trade with the new world, persuaded the Emperor of Austria to an arrangement under which the latter, after retaining sufficient for use in Austria, made over to the Spaniards the whole surplus output of the mines at Idria. The Spaniards carried on a very profitable trade with the mercury which they bought at their own price from Austria, and sold at their own in America. Spain thus remained mistress of the market, although no longer the exclusive producer of the metal. She took from Austria, every year, 368 tons of mercury, at £240 per ton, reselling it at £360 per ton. At about this time negotiations were being made with the famous Fugger family by the Spanish government for ceding to them the right of working the Almaden mines and reducing the cinnabar. This concession was enjoyed by the Fugger family from 1525 to 1645, and enriched it enormously. Its members became princes of the Roman empire, and accumulated one of those colossal fortunes at which history is amazed. Their name, Ibericised into the form *Fucar*, became a synonym for wealth, and the Spanish proverb, "richer than a *Fucar*," is still current.

The mines discovered in Germany and Tuscany being of no great importance, the only apprehension of the Spaniards was to see China, who was supposed to possess enormous deposits of cinnabar, appear in the market as a seller. The contrary, however, has really happened, China being a buyer in the markets of both Europe and America. Just when no such thing was being thought of by any one, new discoveries were made, on such a scale that the former conditions of the mercury market have entirely passed away.

At the time of the gold fever in California the gold-finders in the Trinidad placers used to come across grains of reddish stone of so high a specific gravity that on washing the sands they always settled at the bottom of the cradles, after lighter matters had been removed. The name of "red stuff" was given to it by the miners, just as that of "blue stuff" was given to other numerous fragments of a bluish color. The first were cinnabar, the second an extremely rich sulphate of silver.

In a country where science and action are both practical, and easily come together for the common good, these indications were speedily utilized. When the importance of the "placers" became less, investigations of a very costly nature were set on foot. At the cost of labors which would have discouraged less energetic and enduring men, the veins were discovered which are now great sources of wealth. At the present time New Almaden, New Idria, Napa, Colusa, Sonoma and Lake counties, afford ample field for the energies of that puissant race, which to its unrelenting exploration has added unrelenting winning, and to these an unrelenting progress in the methods of treatment of the output. Three patents for distilling furnaces are in existence: Randol's, Knox & Osborn's, and Livermore's. These are for treating poor ores, either in cakes or in a pulverulent condition. Ores differ very considerably in richness, the range being from 20 to 2 per cent. All has been the work of less than a quarter of a century, and at the present time more than half the world's consumption of quicksilver is yielded by that privileged country.

The metal is brought to market in iron flasks holding 76 pounds (34.5 kilogrammes) of mercury. Of the total annual production of 100,000 bottles, 60,000 come from California. From the port of San Francisco, where the greater part of this is shipped, there having been forwarded, during the last 15 years, 400,000 bottles, of the total value, in round numbers, of £2,850,000. New Almaden, which for some years has been the most productive mercury mine in the world, produced 34,765 bottles in 1862, 40,391 in 1863, and 47,191 in 1864. The highest output in any year of the original (Spanish) Almaden mine was 32,336 bottles; its annual rate at present is restricted to 9,000 bottles. The results of the American production have been, in the first place, to arrest the upward tendency of the price of quicksilver, and, in the second, to increase the stock, as shown by the contrast between the 23,591 bottles entered at New York in 1874, and the 41,165 entered in 1875. In the third place, the consumption has so increased that China, which in 1873 took 1,900 bottles, figures in the statistical accounts of San Francisco in 1875 for 18,190 bottles; while Mexico, which in the first of these two years limited its demands to 3,761 bottles, took 5,757 in 1875. Lastly, the home consumption on has been enabled to rise to 15,000 or 20,000 bottles a year, which is the quantity retained by the States for their own use. The California mines produced last year a total of 40,900 bottles, distributed as follows: Redington, 13,000 bottles; New Almaden, 9,000; New Idria, 8,800; Guadalupe, 3,400; Great Western, 3,400; Saint John, 700; Liverdale, 700; Buckeye, 700; Manhattan, 450; Great Eastern, 400; Phoenix, 350. The weight here shown is about 1,420 tons. The production of Sulphur Bank, which takes the second rank among American quicksilver mines, and that of several mines of less account, were not included in the document from which we extracted the foregoing figures.

We can now see to what an extent the market has been modified. Spain has never been in a position to offer more than 40,000 bottles a year; the Almaden furnace now producing a standard of 25,000 bottles, and she standard consumption being about 100,000 bottles. The difference is furnished by other sources of supply than Spain. The quicksilver market, therefore, it is self-evident, is no longer a monopoly of Spain. It was ours so long as we were the only producers, but England, for whose custom all producers are desirous, as she consumes on her own account about half the total product, or say 45,000 bottles, has become the field of competition, and the market has been transferred to London. To this change the house of Rothschild has contributed by the share it has taken in quicksilver transactions, the possession of the Spanish mines having been made over to it for a certain number of years. [The house of Rothschild acquired the right to work the Almaden mines by a cession made in consequence of a contract entered into with the Spanish government in 1843.]

Fortunately for ourselves, the heavy cost which the California mercury has to defray for carriage before it can make its appearance on the London market, as well as other charges which it has to bear before it leaves its port of exportation, affects it sufficiently to tell very decidedly in our favor, and make our competition possible. The time, however, is come when we would do well to rouse ourselves from any dream of undisturbed possession, and endeavor to get all the profit we can out of conditions which we are not in a position to annihilate.

The decided tendency to rise which was marked before the discovery of Californian cinnabar has not only not been contra-indicated, but there has been a considerable decline.

The two principal elements of price are the cost of raising and the cost of purifying.

The first of these elements, the cost of raising, may as well stand out of the discussion; labor is dear at Almaden, as treble pay is given. This cannot be avoided; since the miners cannot work more than three hours a day without being poisoned. But any reduction in the cost of raising would tell very slightly on the cost of the metal, since even the triple pay brings up the first charge to only 2s. 6d. per cwt. The question is thus limited to one of treatment of ore, and it is in this that we in Spain have to confess room for improvement.

The furnaces in which distillation is carried on at Almaden are those of Bustamante, invented by that distinguished engineer in 1648 (that is to say, at the time that the Fuggers gave up the mines), and the so-called Idrian, introduced in 1806. This latter year is the latest term of improvement. Idria itself, however, has twice since then reformed its distilling, and in California, as we have already stated, there are three patent systems in use. As it is reasonable to suppose that each and all of these newly-introduced systems have improved on the older ones, this mere recapitulation shows us as very much behindhand.

The treatment of cinnabar is difficult, on account of the volatile nature of mercury, which, if not prevented, escapes with the products of combustion. The damage done by mercury fumes are specified by Dr. Roberts in a remarkable work treating of Berrens's system, by which evaporation is completely avoided.

The ordinary estimate of the loss by evaporation in the Almaden mines is 50 per cent. The result of an experiment by the celebrated engineer Escosura, who obtained a minimum of loss of 4.36 per cent., has sometimes been looked upon as a standard; but the results obtained in a laboratory cannot for a moment be compared with practical furnace-work as carried out at Almaden. Senor Monasterio, director of the Madrid school of mines, was commissioned some years ago by the government to report upon the system proposed by M. Pellet, a French engineer, as compared with that followed at the Idria furnaces. He reported unfavorably to Pellet's system, and it is therefore to be supposed that he did the best he could with the San Luis furnace, on the Idria plan. The percentage of loss stated by him was 5.59 per cent.; but the figures are open to question—firstly, for the same reasons as those given in reference to Escosura; and, secondly, from the testimony of M. Huyot, who (*Annales des Mines*, 1852) states the loss at Idria to be 27 to 29 per cent. Senor Monasterio concludes his report in the following words: "Can it be supposed that, under normal circumstances, when one has not the same interest (i. e., in the ordinary course of working), the loss rises to twice the amount? Even then, it would only be 20.16 per cent., or less than half the amount which has been stated in public documents." It would almost seem as if Senor Monasterio were satisfied with 20.16 per cent. of loss—which, by the way, comes very near to Huyot's estimate of the loss of the Idria furnaces. Letting it, however, stand at this, and supposing that the mines at Almaden have produced to a value of £60,000,000 since the establishment of Bustamante's furnaces, the proportionate loss will be not less than £12,000,000.

The ratio of loss in the patent furnaces used in the United States I am not acquainted with, but I cannot conceive it possible that the Americans would look without concern on the loss of such immense quantities of mercury, discharged uselessly into the atmosphere. It is very possible, therefore, that we are seriously at a disadvantage, relatively, to the mines of California.

The advantages which the Almaden mines possess over their rivals beyond sea are very considerable. In the first place, their ores are much richer than those of California; the preliminary costs have been long since defrayed, and the seams are of great thickness, some workings being 12 feet, others 15 feet, and others nearly 30 feet thick. Spanish quicksilver, too, can be put on the English market at only a fraction of the freightage paid by Californian metal. These are conditions which ought to turn the balance in competition, and if the increasing consumption of America absorbs its output, as it tends to do, the market of Europe can and ought to belong to Spain.

Almaden only raises four tons of mercury a day or 25,000 bottles, the seven months of working. [The furnaces are closed from May to September on account of the heat.] England wants 45 tons. Since we could let her have them, why do we not?

Fortunately for Spain, an improvement is at hand. A distinguished chemist of Barcelona is now testing at Almaden a furnace of his invention, which is reported to save the whole amount of the mercury distilled, whatever the quality of the ores. The tests were conducted in the presence of a commission of three mining engineers specially appointed by the government.

Two experiments were made. In the first, the inventor, Senor Berrens, operating with great care, obtained a quantity of mercury equal to the proportion contained in the ore, less 0.79 per cent. In the second, the inventor, so far from operating with care, seemed to act with studied recklessness, and the commission were

surprised to see the ordinary precautions totally abandoned. The inventor hastened the period of roasting; he drove the steam engine at the rate of 126 strokes a minute, he shortened by 25 hours the time taken for roasting in the previous experiment, and raised the temperature of the furnace to a white heat. He did all that could be done to entirely ruin the operation, and yet the loss did not exceed 3.62 per cent. Indeed this loss was apparent only, not real, for the leaf of gold placed at the top of the flue did not show the smallest trace of mercurial change, proving that no loss by evaporation had taken place. This was acknowledged by the commission, which allowed that the mercury thus wanting might be deposited in a part of the apparatus contrived *ad hoc*. The object of the inventor in his second experiment was to show that his system was not easily prejudiced by careless working.

The Berrens furnace has the further advantage of remaining in use all the year round. The two experiments were carried out in August at an exterior temperature of 27° to 33° C., so that without increasing the proportion of work, the 25,000 bottles produced in seven months could be raised to 43,000 bottles, working all the twelvemonth through.

The reality of this important improvement has been testified to by competent authority of the commission, which presented its report last January.

Manganese.

The following letter, from a leading Boston house—Hobbs, Pope & Co.—explains why it was written. We publish it on account of its valuable information, relative to the varieties and the whereabouts of manganese:

Editor American Manufacturer:—I have read in the issue of your paper of 7th inst. an article headed "A Manganese Mine that Beats Gold," taken from the Atlanta (Ga.) *Constitution*. Editorially, you explained the misstatements or errors the above article contained as relating to ferro-manganese, and with your permission we would call attention to the statements made concerning manganese. As miners, shippers and dealers in manganese, we have acquired an intimate acquaintance with this ore and the mining of it, and would beg to call attention to a few of the statements made in the article referred to. The assertion that manganese is exceedingly rare is entirely erroneous, when it is well known that nearly every State in the Union produces it to a greater or less extent, as well as all the provinces of the Dominion of Canada. The mines of England, Saxony, Spain and Turkey, mainly supply the European markets with ore. Hardly a week passes that we do not receive samples of manganese ore for examination from some section of the country, but the greater proportion of them are of a low grade and unworthy of attention. The deposit of ore in Bartow county is described as the "richest, longest and purest" to be found on this continent; we hardly know what is meant by "longest" in this connection, but having examined many samples of ore from Georgia, we have never known of any quantity of ore obtained from that section which could be described as remarkably rich or pure. The fact is that manganese of high test and superior quality is obtainable only in limited quantities; were we able to obtain more than a sufficient quantity of this description to supply our home trade, we could find a ready market for such surplus abroad at good prices, while the medium and lower grades of ore, which are obtainable in almost any desired quantity, will not often pay to ship in competition with the European mines. The statement that there is enough manganese in Bartow county to manufacture 50 tons of ferro-manganese per day for 50 years is a very loose statement, which cannot be demonstrated, and certainly shows ignorance on the subject of manganese mining. It is not found in "inexhaustible beds" like coal, but its deposits are very unreliable, it being almost always found in "pockets," or in "veins" or "seams," which can never be relied upon as carrying ore for any specified distance; it is, in fact, next to impossible to estimate the yield of a manganese mine for any specified time beyond the immediate future.

In conclusion, one point in the article surprises us more than any other, which is, the fact of openly stating to buyers of ferro-manganese the enormous profit which the owner of this "bonanza" will receive from them, which course we should hardly think advisable for his interest.

NEW EMERY STONES.—A German technical publication gives some particulars of a new kind of polishing stone manufactured by Van Baerle & Co., (Worms, Germany), and consisting of emery, soluble glass and petroleum. The emery stones in general use consist of gum, shellac, and emery. When stones of this description are turned rapidly, either dry or with oil, they get heated to such an extent that the gum or shellac becomes soft, the stone turns greasy, and does not act any longer. The new stones are said to be free from this objection. Their speed may be increased from 1,000 to 2,000 revolutions per minute, according to the size of the stone. When they are used for polishing steel, the latter does not get heated to such an extent as with other stones; the steel does not become annealed, and preserves its hardness. The new stones are damped by means of a rag soaked in petroleum and oil, and are made in three shades of fineness—fine, medium, and coarse.

Vipond Mines and Machinery.

The *New Northwest* (Montana) says: The mining regions of Quartz hill and Vipond, in Beaverhead county, can now hold up their heads. The Monroe mining company has completed and put in operation its mill and for the last four weeks it has been running continuously without stoppage of any moment—and shipping silver.

Retrospective.

The localities named have not been very prominent before the Montana public; there never has been any particular excitement about them, or stamped to them, but the few proprietors owning leads have been feeling satisfied with the prospects before them, and have been quietly sinking their shafts and accumulating ore on their dumps, building roads and bridges, awaiting the day when the value of their mines would be recognized to an extent which would encourage some one to build reducing works within reach of their ores. They manifested their faith in their mines by one undertaking which at least proved their indomitable energy—they built a road from Divide to the mining region, which for three miles, through a canyon of the Big Hole river, surmounted more difficulties than are found in any like distance in Montana, besides building a bridge across the river, which has withstood its rapid current successfully. Of course these kind of men compel success and success seems in their grasp.

Character of Ores.

Last spring the ores of Quartz hill were supposed to be of a character requiring the use of the roasting processes in reducing them, their known extent was large, and they were pretty well developed as the country goes. Those of the Vipond district were known to be more base than those of Quartz hill, their extent was also known to be great, some of the veins being, even in this country of wide lodes, very wide. The great trouble anticipated was that the cost of reducing them might be so great that their value would be so lessened as to make them unprofitable to work—their grade having been known to be medium.

Putting up Works.

Last spring one of the owners on Quartz hill, M. Dewey, and his associates, determined not to wait longer, but to ascertain for themselves what could be done with their ores. They accordingly began building an arastra, to be operated by water, furnished from the Big Hole river, a dam having been constructed the year before across the river at the head of Dewey's flat, and a ditch dug the whole length of the flat. Just as these gentlemen had begun their operations, the Monroe silver mining company, through its representatives, appeared upon the scene with the declared intention of moving the Sterling mill to which property they had obtained title, to Dewey's flat, and working the ores of their mine on Quartz hill, as well as doing such work in reducing ores for the miners as should present itself. The construction of the arastra and the building of the mill went on side by side, until about four months after the beginning of each both were successfully at work.

Free Milling.

Meantime, through the forethought of the Monroe company and some of the other proprietors on Quartz hill, it had been demonstrated by the working of a few tons of their ore at the Centennial mill, Butte, that some at least of the Quartz hill ore, especially that of the Monroe company and of the other proprietors who had had the courage and means to make the trial, were free. One of the most successful mining superintendents in Montana having examined the district pronounced that roasting would be detrimental to them; samples sent to San Francisco for examination had been pronounced to be of free milling ore; consequently the Monroe company changed their plan from that of reducing by roasting to wet crushing. The new Purvine pan had also been brought into use in the trial of the ores at Butte, with happy results, saving a large percentage of the value of the battery assays and producing bullion of a very high degree of fineness. When, therefore, about the middle of October the arastra, and the first of November the mill, began operations, it was with an assurance of success with which but few undertakings have been favored.

Good Results.

Both worked well. Ten samples of ores from many of the leads on Quartz hill have been worked successfully in the arastra, and the baser ores from the Vipond district have been successfully reduced. The Monroe company has just finished a run of 100 tons of their ores with satisfactory results. The ores of both districts prove to be of so free a character that no trouble is anticipated in reducing them at an expense which will enable all the mines to be successfully worked. The Monroe company is adding to its capacity by getting in two of the Purvine pans of the largest size, and with its capital arrangement for handling ores and its efficient batteries, expects to be able to work at least 30 tons per day. It will undoubtedly keep at work all winter. Cold weather has put a stop to the operations of the arastra, but the proprietors are enlarging their producing capacity also, to be ready for larger operations in the spring. The people of the two districts are to be congratulated on the prospects before them, and the Territory at large will hold out to them a friendly and appreciative hand.

USEFUL INFORMATION.

Photography Underground.

We have to record (says the *Birmingham Post*) a novel and interesting application of this most useful art. A few days ago, we believe for the first time, an experiment was successfully made for the purpose of obtaining an accurate picture of some underground workings in a coal mine, the process being effected by means of the oxyhydrogen light, generally known as the lime light, in combination with magnesium ribbon in combustion. The scene of the experiment was the Bradford colliery, Bentley, near Walsall, where a few days ago Mr. Frederick Brown, of Walsall, accompanied by Mr. Chidley, representing the firm of Messrs. Duigan & Co., solicitors of that town, attended at the mine for the purpose of obtaining representations of certain portions of the underground workings to illustrate a question of practical mining which is incidental to a litigation respecting that colliery, and having made some preliminary experiments with magnesium light, came to the conclusion that photography would be perfectly possible under conditions which exclude sunlight altogether. Upon the following day Mr. Brown, attended by one of the proprietors of the mine and the deputies, successfully obtained pictures of the portions of the mine indicated by Mr. Chidley. The photographs, as finished, are not only in themselves valuable for the purposes of evidence for which they were required, but, when viewed in the stereoscope, form perfectly accurate delineations of the places from which they were taken, and, indeed, without an explanation that they had been taken altogether by artificial light, the ordinary observer would suppose them to have been produced by the action of the sun in the ordinary way. The process occupied for each picture was from 25 minutes to half an hour, while the sensitive plate was under the action of the light. One of the principal technical obstacles which Mr. Brown had to encounter in the chemical portion of the process was that the ordinary wet plate, although so much more rapid in its action, would not retain its moisture for the lengthened time of exposure rendered necessary under the altered conditions of light and the well known increased temperature in mines; but this difficulty was, after repeated experiment, admirably overcome by a chemical formula which Mr. Brown was fortunately able to devise to meet the special emergency. The difficulties of focussing arising from the cramped position in the mine were, of course, merely mechanical, but consumed much time to overcome. The result appears important in many ways, as suggesting in future the possibility as well as the propriety of photographing the interior of mines after accidents, and in the course of litigations and the like, for the edification of those who have not had the opportunity of visiting the spots, and yet might have to decide questions respecting them. The possibility, also, of introducing a powerful and steady light completely under control, which may be fed from the surface by means of flexible tubing, and which would enable a light rivaling that of day to be sent into dangerous places from a convenient and safe distance, appears to us to open a pathway to very important practical application.

Fire-Proof Towns.

The *American Exchange and Review* says: While numerous fires destroy about 80 cents in the \$100 annually of the whole combustible property of the United States, and something like one-third of this ratio in Europe, it is yet a curious fact that there are cities and towns almost absolutely fire-proof; that is to say, inflammability, internal hazard and external exposure are reduced to the minimum. Two examples of such flame exemptions exist in Buenos Ayres and Montevideo, two South American capitals, about 100 miles distant from each other, the former of which is still destitute of anything like a sufficient water supply, while the latter was similarly deficient until a few years ago. South American earthquakes make one-story houses the fashion in South America, and one-story houses are poor flame spreaders; and in addition to this, the country around the two cities named is poorly supplied with timber, so the houses have been built with a view to the greatest possible economy of wood, and there is an absence of heat-expanding iron and heat-disintegrating stone. For joists, rafters, etc., the people of Buenos Ayres are compelled by circumstances to use hard woods. The rule in the construction of buildings is, that if a large number of small wooden rods, like canes, be placed—say two inches apart, like a gridiron, over two thin brick walls supporting their ends, a fire made below will burn through a few of the rods that are directly in the flame, and there the destruction ends. In the same manner, if a cart-load of shavings and pine wood were placed under a bed in a Buenos Ayres house, and other furniture piled thereon, and the whole set on fire, four or five of the joists of the floor above would be burned, and the bricks and tiles would fall through, but there the damage would end, for the house could not be set on fire. The mode of building is as follows, the material of the walls being brick. Each floor and the roof, for the latter is quite flat, is supported by joists of hard wood laid about 18 inches apart. Across these are placed rails of the same kind of wood, $2\frac{1}{2} \times 1\frac{1}{2}$

inches, and the space between the latter bridged over by thin bricks, $1\frac{3}{4}$ inches long; another layer of bricks is then put on, and over it a floor of tiles. The roof is made in exactly the same manner, except that it is laid in cement, and has a slant of one foot in 30 to 35. The doors and windows have no boxes, but only frames for the sash, and there is no lathing, nor wainscot, nor skirting. The doors and window shutters are of cedar, or some hard wood that is slow to ignite.

The Permanent Exhibition.

The *Philadelphia North American* says: The permanent exhibition promises to be a grand success, the applications for room being already so numerous as to more than fill the main building, and that fact will give our readers an idea of what the exhibition will be. Many foreigners have applied for space, and it is believed that nearly all the countries represented at the Centennial exposition will secure room in the permanent exhibition for the display of their goods. Those articles exhibited during the summer and fall will generally be removed, to be replaced by other and still better ones, fresh from the manufacturers and artists of this and the old world. The manager has received such an immense number of applications that he will be compelled to make selections from the mass of articles submitted, and by so doing those accepted will be of the best quality, and in numerous instances superior to those of the same character displayed at the recent exposition. The directors design to improve the conveniences of the main building in every possible manner, especially in widening the passages and avenues, and introducing such other changes as may be deemed necessary to facilitate the movements of large crowds and give visitors better opportunities to view the exhibits. The success of the permanent exhibition is assured beyond a doubt, and we have no fears but it will be conducted in such an enterprising and liberal spirit as to merit the support and well wishes not only of Philadelphia, but of the country.

BLEACHING WOOL.—MM. Daudier & Son thus describe a new process for bleaching wool. It consists in plunging the wool or vegetable matters into a concentrated bath of chloride of calcium, and submitting them to prolonged boiling; to the bath may be added some hydrochloric acid, or compounds of that acid with metallic bases, such as aluminum, iron, zinc, copper, or tin, which will then act energetically on vegetable matters, while it will produce no alteration on wood.

GOOD HEALTH.

Air for Infants.

We cannot lay down any rule with regard to exposing infants to the outer air, but we know they must have it in some way. Mothers must be discreet and not expose their infants to so low a temperature that even their warm clothing cannot retain sufficient animal heat to resist the depressing influence of cold. The extremes of temperature must be lessened by good management. The heat of summer can be lessened in its effects upon infants by keeping them in cool rooms during the heat of the day, and in warm rooms (no: hot) during the cold; exposing them to the outer air in the former case morning and evening, and in the latter case, in the warmest hours of the day.

In the damp, chilly temperature of spring and autumn, when the special diseases of infancy are apt to prevail, too much care and watchfulness cannot be bestowed. Adults, barely able to move their bodies, have been strengthened and raised to a good degree of health by being placed in some convenient carriage and taken out to ride daily. In the same way sick infants may be wonderfully improved by being taken into the outer air and given gentle exercise. By it the strong are made stronger and the weak are rendered less feeble. We have known infants so feeble that the fresh air was their only medicine, and on this they recovered. Compare rural with city children. The pale faces and soft muscles of the latter do not compare well with the ruddy faces, hard muscles, active limbs and sprightly eyes of those who spend most of their time, every proper day, in the open air.

While we regard the purity we are not to disregard the temperature of the inhaled air. The mother's plan should be to preserve as uniform a temperature as possible. For it is not the absolute temperature that harms infants, so much as the vicissitudes of it. A house in mid-winter should not have a temperature higher than 70° Fah. It is this difference that does the harm, the sudden change from heat to cold. Let me repeat, mothers should not suppose that because harm does not follow exposure at once no harm has been done. Ordinarily the bad influences of indiscreet exposures appear gradually. Some infants are more predisposed to "take cold" than others. Some are very susceptible to vicissitudes of temperature. They may be but slightly exposed on some damp, chilly afternoon. They are put to bed in apparently a good state of health. They do not sleep well. The next day they are hoarse, and by night are feverish, and in a few hours may have indications of sore throat, or inflammation of the lungs, or croup. What shall a mother

do? If she expose her infant to a lower temperature than that to which it has been accustomed, it may take cold. If she keeps it snugly warm within the nursery or the house, it becomes very tender and susceptible, so that, on the whole, she may find, as others have, that her infant is safer, less likely to take a severe cold, if discreetly exposed, than if confined to the hot air of her dwelling.

The most and best a mother can do on this subject, is to collect from the wise and experienced in the business of raising children all the knowledge they have, and then use her discretion in its application. The greatest wisdom and the keenest discretion cannot always protect infants in such a way that they never "take cold." A young mother, then, needs the advice of those who have obtained their wisdom by experience and observation. She must not judge of the proper temperature for the health and comfort of her infant by her own sensations. She must have in use a thermometer, so that she may know exactly what the temperature is in the nursery and in the outer air. Our feelings are not trustworthy thermometers.

Feeble children, in whom the powers of resistance are small, should be guarded against exposures in damp and chilly weather. Fresh air contributes to the health and comfort of infants, but severe cold is an excess of freshness and may injure on the general principle that moderation benefits and excess harms. A vigorous child, who can easily resist the depressing influences of cold, and who is so warmly clothed that it can retain the animal heat generated by the various functions of his nature, is ordinarily very much benefited by inhaling cool air. It renders him still more robust and hardy. It improves his digestion and his assimilation. It enriches his blood and gives strength and rapid development. The weakly and poorly developed do need great watchfulness from the mother. We repeat, the comfort and health of infants requires discretion in exposing them to unaccustomed degrees of cold.—*Prairie Farmer.*

Poison in Blue Cloth.

EDITORS PRESS:—While the papers are discussing the properties of poisons in different articles of wearing apparel, I wish to give my experience with a very common garment, "blue overall cloth." Twice I had a milking jacket made from the same material, and twice I have suffered and am now suffering from its poisonous condition. The arms appear inflamed, especially at the wrists, where the cloth comes in contact with the skin, and the itching thereby is intolerable. For some days I could not account for the affliction, until I remembered having had the same symptoms when I first put on a former jacket. I immediately sent the blue vestment to the wash-tub, the washer being poisoned in one washing.

As blue color is generally made from green and yellow, it is very probable that "paris green" is used. If so, no wonder it produces the itch. [See note below.—*Eds. Press.*]

The cloth is so universally worn as overalls that much evil may be caused from the effects of the poison without knowing the why or wherefore. Let any person who wishes to test the above facts procure a small strip of the goods and tie it around the wrist, and if inflammation takes place, with a desire to allay the itching, they will find by experience the truth of my statement. **JOHN TAYLOR.**

Mt. Pleasant, Dec. 11th, 1876.

[Our correspondent is doubtless accurate in his experiences, but he is at fault in his surmises. A blue color is not and cannot be produced by a combination of green and yellow. Blue is a primary color and cannot be produced by any mixture whatever. Our correspondent is doubtless misled by the memory that blue and yellow produce green by mixture. There is no "paris green" in any blue dye, and our sufferer cannot attribute his discomfort to this cause. Blue dyes were formerly made almost wholly of "prussian blue" (prussiate of iron), but of late the introduction of aniline colors has been general. We have read of poisoning by aniline dyes, and here may be the trouble. So far as the practical effects of the cloth are made known by our correspondent, his contribution is of general value and should be heeded.—*Eds. Press.*]

AVOID CHILLS.—It is one of the facts best known to science that when a part of the outer surface of the body has been exposed long to cold the greatest risk is run in trying suddenly to re-induce warmth. To become thoroughly chilled and then to pass into a very warm atmosphere, such as is found near a fire, results in a dangerous reaction which, a few hours later, may cause pneumonia, or bronchitis, or both diseases. The capillaries of the lungs become engorged, and the circulation becomes static, so that there must be a reaction of heat inflammation before recovery can occur. Common colds, says a contemporary, are taken in the same way; the exposed mucous surfaces of the nose and throat are subjected to a chill, then they are subjected to heat; then there follows congestion, reaction of heat, pouring out of fluid matter, and the other local phenomena of catarrh.

MINING SCIENTIFIC PRESS

W. B. EWER..... SENIOR EDITOR.

DEWEY & CO., Publishers,

A. T. DEWEY, GEO. H. STRONG,
W. B. EWER, JNO. L. BOONK.

Office, No. 224 Sansome Street, S. E. Corner of California Street, San Francisco.

Subscription and Advertising Rates:
Advertising Rates. 1 week. 1 month. 3 mos. 12 mos.
Per line..... .25 .80 2.00 5.00
Half inch (1 square). \$1.00 \$3.00 7.50 24.00

Four weeks are rated as one month.
Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing in extraordinary type or in particular parts of the paper inserted at special rates.

Subscriptions, payable in advance: For one year, \$4; six months, \$2.25; three months, \$1.25. Remittances by registered letters or P. O. orders at our risk.

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription.

THE ORIGINAL ARTICLES in this paper are mostly set in solid type, giving in our columns one-third more reading than is contained in ordinary leaded matter.

ADDRESS all letters to the firm, and not to individual members, or others, who may at any time be absent from our office.

Our latest forms go to press on Thursday evening.

SAN FRANCISCO:

Saturday Morning, January 6, 1876.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Mechanical Ore Concentration and Separation, No. 16; Kemp's Boiler Cleaner, 1. A New Volume; Bullion Product of 1876; Academy of Sciences, 8. Improved Screw and Bolt Cutting Dies; A Self-Lighting Lamp Burner; The Two Leading Industries of the State at Variance, 9-12. Ashblat, Disaster, 12. The Drouth; Patents and Inventions, 13.

ILLUSTRATIONS.—Kemp's Improved Boiler Cleaner, 7. Improved Screw and Bolt Cutting Dies; Excelsior Self-Lighting Lamp Burner, 9.

CORRESPONDENCE.—Mining, Etc., About Helena, M. T.; Santa Cruz Water Works, 2-6.

MECHANICAL PROGRESS.—Rules for Tempering Steel; A Note on Files; Welding; New Way of Making Miners' Picks; Make Your Inventions Known; New Railway Carriage, 3.

SCIENTIFIC PROGRESS.—Caterpillars in Coal; Spectra of the Planets; Murder of Scientists; The Moon's Motion; Cause of Error in a Thermometer; Climatic Changes in Russia; Siderophthite, 3.

USEFUL INFORMATION.—Photography Underground; Fire-Proof Towns; The Permanent Exhibition, 7.

GOOD HEALTH.—Air for Infants; Poison in Blue Cloth; Avoid Chills, 7.

MINING SUMMARY from the various counties in California, Nevada, Arizona, Colorado, Idaho and Utah, 5-12.

GENERAL NEWS ITEMS on page 12 and other pages.

MISCELLANEOUS.—Quicksilver; Manganese; New Battery Stones; Vipond Mines and Machinery, 7. The Barometer as an Indicator of Gas in Collieries; Tea-Preparing Machine; Measurements of Angles by Bees; Fatal Result of Too Much Curiosity; The Indian Cyclone; Bleaching Cotton; A Natural Curiosity; Fine Cutlery; An Iron Torch; Car Wheels; To Make Leeches Bite, 10.

NEW ADVERTISEMENTS.

Baxter Steam Engines, Baker & Hamilton, S. F.

BRUCKNER'S ROASTING FURNACE IMPROVED.—We had the pleasure a few weeks since of meeting Mr. Bruckner on an overland train on his way to Colorado, whither he was going to examine and re-fit quite a number of his furnaces, which have been in operation there for several years. Mr. B. showed us the drawings of several improvements in his furnaces, which he is now introducing wherever new ones are put up. During his ten years' absence in Europe he has introduced a large number of these furnaces into various mines in Germany. He has also invented an improved apparatus for pulverizing quartz, which he assures us has been thoroughly tested at Freiberg and pronounced a success. He claims a large economy in the process of reduction, more efficient pulverization and a great reduction in the cost of the machinery. Mr. Bruckner will soon visit this city to make arrangements for the manufacture here of his improved machinery.

SECRETARY ROBESON has assured the secretary of war that the navy department will cordially co-operate with the war department in the daily simultaneous meteorological observations now being made by many nations around the world.

ABOUT two out of every three passengers on the train which fell through the bridge at Ashblat were killed by the fall, the fire or the cold.

COMMODORE VANDERBILT died in New York on Thursday last. His death has been expected for a long time.

THE telegraph reports that the snow storm of Monday and Tuesday throughout the Eastern States was the heaviest for several years.

THE December progress in the Sutro tunnel was 327 feet.

A New Volume.

With this issue the MINING AND SCIENTIFIC PRESS enters upon its thirty-fourth volume. The paper appears to-day in an entirely new dress of type, which is but an indication of renewed prosperity and a desire to present to our readers a paper worthy in every respect of their patronage and good esteem. The MINING AND SCIENTIFIC PRESS began its existence in May, 1860, and has been published without intermission ever since. It has kept pace with a growing country from year to year, and with its growth improvements have been made from time to time for the benefit of our patrons. It contains now a great deal more reading matter than it did a few years since, as we now use mainly brevier and nonpareil type set solid, where we used to have bourgeois leaded. By this means more space is gained for reading matter, of which we have endeavored to furnish as great a variety as possible.

Situated in the center of the greatest mining field in the world, we have devoted a great share of our space to the mining interests of the country, giving the current news from all localities from week to week. We have paid close attention to all improvements of benefit to the industrial classes, and illustrated such new inventions as appeared to us worthy of special notice.

We consider that during the past year our columns have contained a variety of useful and interesting matter to the mining public, furnished by no other technical journal. Our efforts have naturally been devoted to the development of home industries, but in so doing we have ignored nothing abroad which would be useful at home.

The letters of our traveling correspondents continued through the last volume and to be continued in this, have been of great value. Among the continued articles of interest and value have been those entitled "Facts about Peat," "Quicksilver," "Mechanical Ore Concentration and Separation," "Gems and Precious Stones," "Drainage of the Comstock," etc. The "Comstock Papers" have been interesting as a complete historical record of that great lode. These papers will be continued in this volume. Aside from the continued articles, we have presented the usual variety of reading matter on different topics, and have illustrated such articles as seemed necessary.

We have kept a complete record of Pacific coast inventions, giving weekly—as we shall continue to do—the list of patents issued in Washington, and describing in detail such as are of special interest to Pacific coast readers. In all industrial matters we have endeavored to report progress and give such hints and suggestions as are applicable to the field.

This year we start in with hopes of still further increasing the value of the PRESS. We now have our own press, folding machine, cutter, etc., and send out the paper cut and sewed and ready to be read, without trouble to the reader. We appear to-day in a new dress of type, which, though of course a source of great expense, we feel justified in assuming in order to keep pace with the growing industries which we represent.

We hope during the next few months to be able to present even more original illustrations than heretofore. One of the proprietors of the PRESS is now in the East making arrangements to this end and we hope to introduce the photo-engraving process, which offers better facilities than any we now possess. When these arrangements are made, we shall be able to give more original engravings than we have previously done, and thus still further enhance the usefulness of the paper.

It will be our endeavor in 1877, as before, to continue to improve the PRESS as far as possible and spare no pains or trouble in maintaining its excellence. Our list of subscribers has attained proportions which warrant our making these improvements, and our advertising patronage is of the most respectable character both as to style and amount. Still, it takes a great deal of money to "run" a journal like this, and we naturally desire to increase our list of subscribers. No person interested in mining pursuits can afford to be without the PRESS. It not only gives him the current news, but describes all the new improvements, and gives him the experience of others in the same business. Mechanics also in all parts of the coast should read and foster the journal specially devoted to their interests. We collate from all available sources practical information of value to them, and give them hints worth far more than any subscription price.

The beginning of the new year is a very favorable time to renew subscriptions, or for new subscribers to commence taking the paper. At the end of the volume they have a complete book, closely indexed, appropriately illustrated, and giving facts on a large variety of topics, easily available for reference. The PRESS has now been in existence long enough to prove its worth and to show that it fills its field properly, and we feel justified in assuring any new readers that they will without doubt be satisfied in the investment of subscribing for a year. If our friends will continue to lend their assistance as they have in the past, the paper will continue to improve even more rapidly than heretofore.

Bullion Product of 1876.

John J. Valentine, General Superintendent of Wells, Fargo & Co.'s exchange and banking house, has issued his annual statement of the precious metals produced west of the Missouri river during the year 1876. From his compilation it will be seen that the aggregate yield is the largest of any yet known in a corresponding duration of time, amounting to \$90,875,173—an increase over 1875 of \$9,986,136. This increase has notably taken place in Arizona, Nevada, Colorado and California, while a slight falling off has been apparent in Montana, Mexico, Oregon, Utah, Washington and British Columbia. The largest increase is in Nevada, which produces five-ninths of the entire amount of gold and silver of the United States. From the subjoined statement may be seen the amount of precious metals yielded in the various States and Territories during 1876:

State or Territory	Gold Dust and Bullion	Silver Bullion	Ores & Base	Total
California	\$16,000,569	\$790,308	\$1,711,910	\$18,502,787
Nevada	1,461,071	44,725,802	4,312,074	50,500,947
Oregon	62,372	220,095	1,62,372	1,62,372
Washington	1,413,608	220,095	35,000	1,668,703
Montana	2,162,208	774,284	350,000	3,286,492
Utah	62,574	774,284	4,312,074	5,148,932
Colorado	2,829,877	774,284	1,314,109	4,918,270
New Mexico	1,028,281	774,284	18,621	1,821,186
Mexico	10,288	1,028,281	54,212	1,141,569
British Columbia	1,441,568	1,028,281	54,212	2,524,061
Totals	\$25,080,570	\$51,808,064	\$13,986,543	\$90,875,173

The method and form of the foregoing is exactly similar to that of statements which we have compiled since 1870, wherein no attempt was made to show the amount of gold contained in silver or dore bullion, or the lead and copper in base bullion; but the violent fluctuations in silver as compared to gold during the present year renders an analysis desirable, and no pains have been spared to arrive at a correct conclusion.

In round figures, of \$37,000,000 produced from the Comstock lode this year, \$17,125,000, or quite 46 per cent., was gold; of the whole product of Nevada 35 per cent. was gold, and of the total silver product, so-called, \$18,647,925, or 31 per cent. was gold. The gross yield is constituted as follows: gold, \$44,328,501; silver, \$41,506,672; lead and copper, \$5,040,000. Total, \$90,875,173. It is possible that the falling off in Montana is more apparent than real, as not so much base bullion and ores by \$250,000 is credited as was claimed for it. A large gold yield is often claimed for Arizona and New Mexico; but as \$2,710,000, or an average of less than \$100,000 per year, is the total amount deposited in the United States Mints since 1848 as from those territories combined, such claims cannot well be substantiated.

Various discrepancies have arisen in the estimates of United States officials of the amount of gold and silver produced in the various years. For instance, 1871, which was a more productive year than 1870, is estimated as yielding ten millions of dollars less. From this fact, and various other discrepancies, Mr. Valentine infers that there is universal exaggeration as to the sum total of gold and silver produced throughout the world. In the past year the United States has produced in silver \$41,000,000, in gold about \$45,000,000. Other countries have produced in silver, \$36,000,000, and in gold \$56,000,000. The lowest price paid in London for silver per standard ounce was 46½ pence, the highest 53½ pence. The exports of silver to India and China have been larger this past year than in any previous one since the Sepoy rebellion, and the railroad era in India during 1856-7, when a total of \$145,000,000 was registered. A comparison of years shows that the gold product of the world was a trifle larger than that of the last two years, but smaller than that of any previous year since 1851. The deficit is about equally divided between the gold producing countries. On the contrary, silver has steadily advanced, noticeably in the United States, and records a sum twice the amount of that registered early in the fifties. Since the demonetization of silver in Germany it is estimated that \$40,000,000 have been sold by that government, with \$80,000,000 remaining. In case the legal tender and national bank one-dollar notes should be retired and silver substituted, \$100,000,000 would not be regarded as excessive for the use of the United States. For the great depreciation of silver in the past year there does not appear a very satisfactory explanation when comparing the actual demand with the actual production.

The following is the product for a series of years according to Mr. Valentine's estimate:

Year	Gold, etc.	Silver	Gold
1871	\$2,100,000	\$20,286,000	\$23,386,000
1872	2,250,000	20,527,500	20,459,453
1873	3,450,000	28,352,100	40,456,593
1874	3,800,000	20,498,000	40,103,405
1875	5,100,000	34,043,010	41,745,147
1876	6,040,000	41,606,672	44,328,501

Academy of Sciences.

The annual meeting of this society was held on Tuesday evening last. The business transacted consisted of the reading of reports of officers.

The report of C. G. Yale, Recording Secretary: The academy held 24 meetings during the year, with an aggregate attendance of 623, and average attendance of 26. Fifty-one papers on scientific subjects were read by members of the academy. Two life members were elected, and two died, leaving the present life membership 79. Thirty-seven new resident members were elected, and 44 were dropped from the rolls for non-payment of dues, and 7 resigned, leaving 287 resident members. Aggregate life and resident members, 366.

The report of E. F. Hall, Jr., Treasurer, showed that the society disbursed \$10,283.31 last year, and that the receipts were something less, so that about \$2,000 deficit must be provided for.

Mr. Harford, curator of the museum, read his report, showing the condition of affairs in the different departments, and the progress made by the curators. The expenditures in the museum for the past year were \$1,450.

President Davidson read a very interesting address, reviewing the progress of science on this coast and the field open for it. He took occasion to say that though the Academy was for the first time a borrower, this was no cause of alarm or uneasiness. They had confidence in the strength of their position, and see clear daylight beyond. The collections were made available for study and comparison, and he believed the broad aims and policy of the Academy would be sustained.

The election of officers for the ensuing year, as certified by the Board of Election, was then announced. There had been no opposition ticket, and the old officers were therefore declared unanimously re-elected, as follows:

President, George Davidson; First Vice-President, Henry Edwards; Second Vice-President, Henry C. Hyde; Corresponding Secretary, Dr. A. B. Stout; Recording Secretary, Charles G. Yale; Treasurer, Ed. F. Hall, Jr.; Librarian, Charles Troyer; Director of Museum, W. G. W. Harford; Trustees, D. D. Colton, R. E. C. Stearns, Thos. P. Madden, Wm. Ashburner, George E. Gray, R. C. Harrison, John F. Miller.

The President announced that in accordance with the annual custom and privilege under the by-laws, the Council of the Academy had recommended for life members Dr. A. B. Stout and Henry Edwards, Esq., for valuable services to the Academy. On motion, those gentlemen were elected.

Our New Dress.

The PRESS is rather proud of its new clothes and does not hesitate to ask its friends to contrast the new, bright surfaces with the garments which have been laid aside. The donning of new type is an event in the history of any newspaper. It is an indication of prosperity. It is a plain demonstration that readers of the paper rank it so high that their patronage warrants expenditure for improvements. And when the publishers return to the patrons the benefit of their substantial support, it should be the occasion for all friends of the paper to give it another push forward. We trust that the PRESS will thus be received and promoted by every reader.

We think the reader will find the new type much clearer and more legible than the old. It has an open countenance and a frank expression which we much admire. The impression, too, is sharp and well defined, and thus may be the thoughts which are presented. Although it is with regret that we lay aside the old type, which has gained for us so many times the eyes of our readers and the expressions of their approval, we trust that the new may secure renewed and increased favor. With this expression of our hope and purpose, we present the first issue of Volume XXXIV. to the reader.

THE British fleet has withdrawn from Turkish waters. One correspondent says this has no political significance. Another says it is because the Sultan, in an interview with the Marquis of Salisbury, definitely refused to accept the proposals formulated by the Powers.

THE managers of the trunk lines have decided to advance the rates on grain and fourth-class freight between Chicago and New York five cents, making the rate 35 cents on grain and 40 cents on fourth-class.

IN THE House this week Mr. Bright asked leave to introduce a bill for free coinage of silver dollars containing 412½ grains, and that no charge shall be made for converting standard silver bullion into coin dollars.

THE late heavy gales on the English coast have caused very great damage. A number of marine disasters are reported.

THE San Francisco Mint coined in 1876 the sum of \$42,704,000.

Improved Screw and Bolt Cutting Dies.

The accompanying engraving represents an improvement in screw and bolt cutting dies, patented through the MINING AND SCIENTIFIC PRESS Patent Agency, June 6, 1876, by John A. Campbell, of Astoria, Oregon, and Thomas T. Eyre, of Salem, Oregon. Having experienced much trouble in having threads cut for different purposes, where machine bolts are not used, and in making repairs, re-cutting bolts and closing the nuts, on account of cutting and fitting and sometimes cutting too much or not enough, the inventors perfected this improvement. Any mechanic will see at a glance its advantage over the old screw plate. The improvement can be made to suit any style of plate where two dies are used.

In the engraving, A represents the stock or screw plate. For convenience the inventors have applied their invention to a screw plate in which the handles are formed on diagonal corners of the plate, so as to leave the ends of the plate free for the passage of the screws which operate the dies. The recess, D, or slot in which the dies, B, C, move, is made narrower at one end than at the other, so that the narrower die, C, moves in the narrow portion, while a wider die, B, moves in the wider portion, thus providing a shoulder, E, (its upper edge rounding off sharp to prevent clogging) on each side of the slot or recess, against which the larger die will strike when moved toward the smaller die, C. The sides of the slot or recess are made V-shaped in the usual way, and the edges of the dies are grooved accordingly, so as to guide the dies and hold them in place. A thumb or lever screw, f, passes through the end of the screw plate A, so that its end will press against the narrow die C, while another screw, g, passes through the opposite end of the plate, so that its end presses against the back of the die B.

In using this screw plate, the size of the screw to be made is first obtained. The narrow die C, is then set by means of the thumb-screw f, so that when the wider die B is forced up against the shoulder E of the recess D, the screws formed by the two dies will be of the proper size. The widest die is then moved back, so as to admit the ends of the bolt or screw-rod; and, as the screw is finished, the die B is moved up by means of the screw g, until it strikes the shoulders E, thus finishing the screw. These shoulders, E, serve as a gauge for determining the size of every screw.

When the die C is once set, every screw or thread formed by the dies will be uniform as long as the die B is moved up against the shoulders E in making the threads, and by shifting the position of the die C any desired size of screws can be made, thus providing a very convenient screw plate, by which man or boy can cut as many bolts as they wish without the necessity of cutting and fitting by guess, or cutting too much, as is often done; being a great saving of time. It can be adjusted to any bolt or the point of the tap, and all be finished the same, where more than one is wanted, or one cut to any desired size, when set to the size wanted. For further information apply to J. L. Boone, this office.

A Self-Lighting Lamp Burner.

Who that has lighted his match to find the lamp and then made the struggle to remove the chimney and touch the wick before the fire reaches his thumb, has not wished that lamps would light themselves? We give on this page a little engraving of an attachment which promises to do just that. As may be seen from the drawing, the attachment consists of a tube fitted into the burner, with proper fastenings. The upper part of the tube is divided into two parts, the edges of which are turned inward and provided with teeth similar to a saw. By inserting a common friction match into the tube from the outside of the burner, as the match is forced up toward the wick tube it becomes ignited, and is fired thereby to light the lamp. For convenience at night a match can be partly inserted, so as to be pushed further up and ignited instantly at any time.

Our representative at the East writes us that he has seen this little appliance work to his satisfaction. He informs us, also, that should there be any parties who wish to introduce the sale of it on this coast, they may address the "Manhattan Self-Lighting Lamp Company," No. 62 Fulton street, N. Y. Samples will be sent, post-paid, on receipt of 50 cents in currency or postage stamps.

It is said that Tweed is utterly broken down at last and ready to make any terms to bring his troubles to an end. It may safely be predicted that he will surrender all the property still within his control, and make a clean breast of the whole ring business to some prudent, trustworthy representative of the prosecution.

The managers of the trunk lines have decided to advance the rates on grain and fourth-class freight between Chicago and New York five cents, making the rate 35 cents on grain and 40 cents on fourth class. The rates took effect Wednesday.

The Two Leading Industries of the State at Variance.

Differences Between the Hydraulic Miners, Ditch Owners and the Farmers—Important Suits Pending—Progress of the Controversy, etc.

For many years past the farmers owning and cultivating the bottom lands along the several rivers and minor streams that traverse or have their sources near the great auriferous gravel deposits in which hydraulic mining is being carried on, have been complaining of the damage done such lands by the detritus carried down these streams and deposited thereon. The rivers along which this injury has been most extensive are the Feather, Bear and the Main Yuba, although some harm has also been done to the lands lying on or adjacent to Dry creek, Butte county, and to those along the American and Cosumnes rivers, with some little caused elsewhere in the counties most exposed to the encroachments of sedimentary matter. During all the earlier history of these mining operations, when the population engaged therein, being much more numerous than now, constituted the best customers of those who cultivated the soil, buying at liberal prices and consuming largely of their products, the farmers raised no objection to the evil they now complain of, nor did they or any one else then question the right of the

the determination of which was by the miners deemed of more importance than the mere matter of damages, which could in no event have been large, the sum claimed by the plaintiff amounting to no more than \$10,000. Among other questions of moment, these special issues involved that of the right of the miners after having discharged these tailings upon their own ground to run or suffer them to flow into the creeks and rivers adjacent, as well, also, as that of their right to augment the volume of water naturally flowing in these streams by conducting water from other sources, and after using to empty it into them, thereby increasing the quantity of sand, gravel and sediment brought down and deposited by them on the lands below.

The defense introduced a large amount of affirmative testimony on these several points, but, as the jury failed to pass upon them, they were left open and unsettled, except in so far as they might be considered inferentially determined by the finding of the jury on the main issue. A certain amount of damage, though not large, was shown to have been sustained by the plaintiff, and upon what hypothesis this verdict was based, save that the defendants had a right to inflict this damage, it is difficult to conceive. However this might have been, the defendants were themselves so little satisfied with the result of the suit, that they resolved to get rid of further annoyance of this sort by buying up all the lands injuriously affected by

IMPROVED SCREW AND BOLT CUTTING DIE.

miners to run their tailings into the rivers and canyons as they are doing at present. And even for many years after these tailings began to prove troublesome, the farmers did no more than murmur and protest, being deterred from precipitating a legal conflict because of the great expense and the uncertain results that might be expected to attend the same.

Inaugurating Hostilities.

And so matters were suffered to remain until about three years ago, when a farmer named Crumb, owning a small place on Dry creek, Butte county, brought an action against the Spring Valley canal and mining company, to recover damages for injury done his land by the tailings flowing from their mines. This company, washing four or five miles above, con-

ducted operations on a large scale, running a heavy head of water the year round, and, as a consequence, sent down great quantities of these tailings, which were gradually covering up the plaintiff's grounds, a portion of his peach orchard having been destroyed prior to the commencement of this suit. Although Crumb appeared alone as plaintiff in this action, it was understood that he received aid and encouragement from other parties in the neighborhood who had similar grievances to be redressed, it being intended that this should serve as a test case, in which the question of the liability of the miners for injuries of this kind should be judicially determined. This suit was tried at Oroville, before a mixed jury of farmers and miners, and resulted in a verdict for the defendants, the jury deciding that there was no cause of action. While this verdict was, as a matter of course, satisfactory to the defendants on the question of damages, the main issue in the suit, it did not dispose of several

EXCELSIOR SELF-LIGHTING LAMP BURNER.

benefit the same, while for the purpose of reclaiming the tule swamps they will prove of incalculable value.

An Attempt to Procure Seasonable Legislation.

During the last session of the California Legislature, some of the larger and more influential mine owners sought to procure the appointment by that body of a committee to examine and ascertain the amount of damage done and hereafter likely to be done by this mining debris, and suggest what measures, if any, should in their opinion be adopted for averting the same, this committee to report the result of their labors to the Legislature at their next session. This effort, so timely and well worthy of attention, proved, however, of no avail, these legislators either failing to comprehend the urgent and momentous nature of the subject, or being deterred from undertaking a task involving so many new and important questions and beset with such inherent difficulties. Later in the session the Committee on Mines and Mining, to whom this business had been referred, recommended in their report on the subject, that

Special Issues

That had been raised in the course of the trial,

Congress be memorialized for the appointment of a commission of engineers to investigate the matter with a view to having the National Legislature provide some general plan for disposing of these tailings without prejudice to the interests of either the farmers or the miners; and in this shape the matter stands at present, so far as Congress and the State Legislature are concerned.

The Farmers Meet and Deliberate.

Early in the month of January last, the farmers of Sutter and Yuba counties, including some other classes of business men, began holding meetings in Marysville to consider this question and devise some feasible plan looking to its final adjustment. At these meetings a wide diversity of opinion prevailed as to the proper means to be pursued for gaining the end proposed, those present thereat not being agreed in regard to the rights and liabilities of the miners in the premises. These deliberations, however, finally culminated in the appointment of a committee, charged with the duty of preparing a bill to be submitted to the State Legislature then in session, by the provisions of which all hydraulic miners are to be made responsible for injuries of this kind in amounts proportioned to the quantity of tailings they run off, it having been further determined to petition that body for the enactment of a law whereby the damage arising from hydraulic washings may be, if possible, prevented.

They Finally Combine for Aggressive Purposes—The Legal Contest Renewed.

Along in the early part of the summer the land owners, after much conference, began forming associations in the several townships most affected by the accumulation of this hydraulic debris. Towards the latter part of July, James H. Keyes, a farmer residing on Lower Bear river, where he owned and cultivated about 1,000 acres of bottom land, commenced a suit in the Fourth Judicial District against the principal hydraulic miners tailing into Bear river and its tributaries, it being understood that Keyes, in this action, represented the Farmers' Association of Wheatland township, Sutter county. The defendants to this suit consist of 22 different parties, some of them incorporated companies and others individual or partnership concerns; there being included in the number several properties of considerable value, and which are being operated on a moderately large scale, but none that rank among the first class in the State. This suit is brought in equity for the reason, as the plaintiff alleges, that he would, in a court of law, be without remedy. Having set forth his cause of grievance, the complainant prays that by a decree of the Court the defendants be perpetually enjoined and restrained from depositing the tailings and debris of their several mining claims in the channel of Bear river or any of its tributaries, or suffering them to flow therein, as well also as from fouling or polluting the water of those streams, thereby rendering it unfit for domestic use or the purpose of irrigation; and, further, that the defendants be by order of the Court restrained from committing any of said acts during the pendency of this suit, and that the plaintiff have judgment for costs incurred in prosecuting the same. That he has proceeded to seek relief in equity instead of instituting an action for damages in law against each of these defendants is, as the plaintiff avers, because this latter course would necessitate the commencement by him of at least 50 different actions, to say nothing of others afterwards required to prevent a repetition of these wrongful doings, the costs of which would greatly exceed any amount of damages he might hope to recover, even if a judgment obtained against these parties could be collected, which, owing to their being transient and irresponsible persons, it could not.

Damage—Past and Prospective.

In this complaint it is affirmed that the defendants are running these tailings into the streams mentioned at the rate of 8,000,000 cubic yards per annum, they having within the past three years deposited over 20,000,000 cubic yards therein; that the bodies of gravel upon which they are operating are of such magnitude that they cannot be run off in the course of 20 years, during which time, if the sending down of these tailings is suffered to go on without effectual measures being taken to prevent their lodgment upon the bottom lands along Bear river, amounting to some 40,000 acres, these lands will be so covered up as to render them unfit for cultivation, 10,000 acres thereof having already been covered by a stratum of this material to a depth of three feet or more; and, finally, that a part of the complainant's land, of which he has over a thousand acres, has already in this manner been inundated to a depth varying from three inches to three feet, and that more of it would have been so overflowed had he not, at an expense of several thousand dollars, constructed levees for its protection.

The Miners also League Together for Mutual Protection.

Foreseeing in this movement a threatened danger to this entire branch of business, the large hydraulic operators and ditch owners throughout the more central mining counties, resolved, after the example set them by the farmers, to adopt a plan of co-operation for their mutual aid and security, to which end an alliance, styled the Hydraulic Miners' Association, was, in September last, formed in this city, the preliminary steps looking to such an organization having been taken some time

Continued on page 12.

The Barometer as an Indicator of Gas in Collieries.

That the barometer is not so valuable an instrument for indicating the presence of gas in collieries as many people believe is the opinion of many of our ablest mining engineers, although the last mines regulation act requires that after dangerous gas has been found a barometer and thermometer shall be placed above ground in a conspicuous position. At a recent meeting of the Midland Institute of Mining Engineers the value of the barometer was noticed by several of the speakers when discussing a valuable paper on the causes of colliery explosions, read by the President. In it he stated that they must look to some additional indicator as to the presence and giving out of gas in mines than the barometer. During a very low depression of the barometer a short time since, so far as his experience went, no more gas had been reported during that low state of the barometer than there was when it was very high. He had made inquiries about it, and Mr. Daglish, the manager of some pits in Yorkshire, told him the same thing, and he had been very particular in making inquiries concerning it. Mr. Wilson (The Oaks) gave it as his opinion that the barometer was an instrument which, so far as mines were concerned, could be dispensed with, although by act of parliament they were bound to have it. In all cases where he had had the management of collieries he had noticed that if there was a large quantity of gas previous to the barometer falling they had it also previous to its rising. It was the same when The Oaks was closed, and he believed that had the direction of the wind been taken at the time and the temperature of the air, that it would have been found that it was the temperature more than the barometer that had affected the pressure of the gas. As to the variations of that pressure, it had been his practical experience for many years that wherever they had a hot pit and the thermometer had been high they had less gas, and immediately after increasing the current of air, and thus reducing the temperature, they had more gas. The chairman said that many years ago Mr. Taylor read a most interesting paper before the members of the Northern Institute with respect to explosions in collieries, and gave a table showing that most of the large explosions had taken place when the barometer was high, and not low.

Mr. Robinson had known the barometer and the thermometer stationary for 24 hours, except that the thermometer fell a little at night. He had seen the gas come out to such an extent that whilst he could have gone to the pit with a naked light at one time, 20 minutes afterwards he could not have gone 300 yards. That was owing to the wind changing, the barometer having nothing to do with it. When they were troubled with carbonic acid gas, and the wind got to the southwest, all scientific knowledge was of no use. Mr. Maddison said that he had traversed 27½ miles before ever the barometer began to fall, and he had heard the wind whistle by into cracks, which proved that the mercury was too slow for the action of the gas. Mr. Barker, in agreeing with Mr. Maddison, said that he had known in the Oaks pit five hours previously that a change was taking place in the atmospheric pressure before the barometer indicated that such was the case, and, therefore, he agreed with the remark that the mercurial column moved slowly. Engineers who are in favor of the barometer, or otherwise, we have no doubt will agree that the ventilation of a colliery should be of such a character as not to be dangerously affected by any fluctuations of the barometer. We all know that miners depend a great deal too much on the safety-lamp, which they too often think is a shield against danger from any quarter and cause, and it may be that some deputies, and even underwriters, look more to the barometer than they ought to do, instead of seeing that the ventilation at all times was as good as it possibly could be. Had that been done it is probable we should have had less accidents from explosions of gas to record than we have had to do.—*London Mining Journal.*

Tea-Preparing Machine.

We have recently had the advantage of seeing the plan and specification of a tea-drying apparatus patented by Mr. Ansell, of the Dooteriah estate. If this machine does in practice what its inventor claims for it on theoretical grounds, it certainly will be an inestimable boon to planters, and we hope a source of considerable profit to its inventor. Until one of these machines has been actually set up and has stood the test of at least one season's practical trial, it would of course be rash in the extreme to hazard even an opinion as to its merits or defects—so many inventions are simply perfection on paper, and yet, somehow, do not answer in practice. Apparently the main novelty in Mr. Ansell's machine is that he proposes to use steam for drying the tea, and that the apparatus is self-acting. In other words, the steam not required for rolling the leaf by machinery is available for drying it, and the leaf goes in at the top of the machine and comes out at the bottom manufactured tea. Mr. Ansell claims for his machine that it will turn out 150 lbs. of dry tea per hour, or in the working day of 10 hours, 18 m. 60 lbs., with an expenditure of 112 lbs. of wood per hour, or 14 maunds per day; being at the rate of about three-quarters of a maund per maund of tea. According to Mr. An-

sell's plan, too, the heat to which the leaf is subjected can be regulated to a nicety according to the wish of the manufacturer, and the possibility of burning is altogether obviated. In addition to the saving of fuel, it also would appear that Mr. Ansell's machine will economize labor very considerably. On the whole, we must say we are pleased with Mr. Ansell's invention, and if he can do in practice what he claims to be able to achieve on paper—dry a maund of tea with three-quarters of a maund of wood—he has solved one of the problems which all planters have so long been desirous to achieve—economy of fuel in the manufacture of tea.—*Darjeeling News.*

Measurements of Angles by Bees.

The editor of the "Scientific Record" in the *Phrenological Journal* makes some observations as to the structure of the compound eyes of the higher insects, that may possibly furnish a basis for the scientific explanation of the accuracy with which bees measure angles. As most readers are aware, the cornea of the insect eye consists of a single membranous layer of transparent lenses or cells, sometimes hexagonal, as represented in standard works, but almost as frequently round or square, depending on their situation. These cells, or double convex lenses, are about one-third-thousandth of an inch in diameter, and, by a method of experiment calculated to ascertain their thickness, I find it to be in bees about one-fifteen-thousandth of an inch. The cornea is not movable as respects its position, but, by means of a circular muscular band, it can, as a whole, be rendered more or less convex, according to circumstances of vision. If a calculation be entered into, as concerns the accuracy of direction of which convex lenses so minute are susceptible, compared with the lenses of the human eye, it will appear that, whereas the average deficiency as respects the estimation of angles in a trained geometer, is about one degree in ninety, the deficiency as concerns the eye of a bee cannot exceed three-one-millionths of that amount—that is to say, if a human eye may be stated as able to distinguish dimly between an angle of 89 degrees and one of 90, the eye of an insect is, by calculation, capable of distinguishing between an angle of 89 999997-1000000 and an angle of 90. The extraordinary nicety with which building insects construct their works is thus readily accounted for by the extraordinary nicety of perception consequent upon such congeries of lenses, and by the immovability of the eye as concerns its position in the head, without the necessity of calling in a special instinct. The lobster, the eye of which terminates a bulb styled the eyestalk, and has a cornea consisting of square lenses, shows, under extraordinary circumstances, a nicety of perception as concerns direction which approximates to that of insects.

FATAL RESULT OF TOO MUCH CURIOSITY.—The Virginia City (Nev.) papers relate the finding of the dead body of a man employed in the Gould & Curry mine, on the 1700-foot level, on Christmas day. The circumstances attending this mysterious death, so far as they ever can become known in this world, are fully detailed in the evidence. The deceased descended to his station for the last time about 5 o'clock p. m. on Christmas day. He notified the engineer that he would not ring the bell on him for half an hour or more. On reaching the 1500-foot level he rings the cage up out of sight of the station, and that is the last known of him until about 11 o'clock at night, when he is found dead in the north drift from the 1700-foot station of the mine. Instead of using the giraffe and being lowered by the engine to that level, he goes on foot down the incline. This of itself is a difficult task, as much of the way there are obstructions in the latter compartment. All these things go to show that the man was endeavoring to make a visit to the lower levels unknown to any one. Had he used the giraffe, he being alone in the mine, it would have been known that he was in that place contrary to instructions, as will appear from the evidence. The cause of his death was doubtless suffocation, caused by the warm and bad air which was in the drift. The blowers had been stopped and there was no compressed air on the level that day. The thermometer was about 115 and a candle would not burn in the face of the drift. This tells the whole story.

THE INDIAN CYCLONE.—Indian correspondents are forming theories concerning the late cyclone in East India, by which 215,000 lives were lost. *Nature* says: The storm wave swept over the islands to a depth in places of 20 feet, surprising the people in their beds. The country is perfectly flat, and therefore trees were the only secure range. Almost every one perished who failed in reaching trees. A strange fact about the disaster is that in Dakhin Shahabazpore and Hattiah most of the damage was done by the storm wave from the north sweeping down to Meghna. Several theories, the *Times* Calcutta correspondent states, have been started to account for this. One is that the cyclone, forming in the bay, struck the shore first near Chittagong, and went north for some distance, and then turned southward again. Another is that the wind blew back the waters of the Meghna, which rebounded with terrific force when the pressure relaxed. A third supposition is that there were two parallel storms with a center of calm between them. The first or third theory seems most probable, as in Sundep and Chittagong the destruction came from the south.

Bleaching Cotton.

Some of our readers may find it a great convenience to be able to bleach a few hanks, or short pattern warps, in order to get samples round quickly; therefore we give the following safe method, from the *Textile Manufacturer*:

Boil well your twist, having first put in the water two ounces of soda ash to the gallon of water; wash off in cold water. Mix one pound of fresh chloride of lime in two pints of water, crushing all the lumps, and then add 43 pints more water. After allowing time for the lime to settle, pour off the clear chloride liquor, and immerse the yarn for about seven hours, in a cool place. Care must be taken to keep the chloride solution and the yarn from contact with iron. Wring out and wash in cold water, and do not allow the yarn to remain in the air very long. Then immerse in a well mixed solution composed of 26 drachms of double oil of vitriol to 45 pints of water. Allow the yarn to remain in this acid solution 10 hours, then wring out and wash off in cold water. In order to thoroughly remove the acid, work it well through a good white soap bath, and to this add a little marine blue to give the yarn any desired tint. Finally wash through warm water to clear away the soap. These proportions will do the least possible injury to the strength of the yarn. The solutions may be used stronger if it is desired to shorten the length of time of the processes. If soft mule yarn has to be bleached, the solutions may be used about one-third weaker; but if doubled yarn, the strength of the solutions must be increased according to the perfection desired in bleaching.

A NATURAL CURIOSITY.—The *American Manufacturer* says: In the great valley between the North and South mountains, in Pennsylvania, commonly called the Eastern ridges, a well was dug some years since in Franklin, and another in Cumberland county, 30 or 40 miles from the former, which led to a discovery affording a subject for interesting speculation. After proceeding in each instance to the depth of about thirty-six feet, the bottom of these wells gave way (but fortunately when the workmen had retired) and a torrent of water rushed up. A lead was sunk with fifty fathoms of line without finding the least obstruction. They remain at this time untouched and of unknown depth. The presumption is, that there is a subterranean lake in that quarter, and how far it extends under the base of the vast primitive mountains situated between the Susquehanna and Pittsburgh, will never be ascertained, unless by some terrible convulsion of nature they should be precipitated in the tremendous abyss.

FINE CUTLERY.—We read in an exchange that a silversmith and electro-plater, of Sheffield, England, has been favored with an order for the manufacture of 20 swords and scabbards, intended for presentation to an Indian princess. At the commencement of this year a durbar will be held at Delhi for the purpose of proclaiming Her Majesty, the Queen, "Empress of India." On that occasion the weapons referred to will be presented to the princess, as well as a number more which are being manufactured in the country. The sword blades are made of the finest Damascus steel, treble tried, and they are mounted on hilts of solid silver, with handles of carved ivory. Each blade is beautifully etched, and upon the hilts are embossed the national emblems. On each of the scabbards is the locket of Lord Lytton, and on each of the hilts is emblazoned his lordship's coat of arms in enamels. The straps, tassel, etc., are enriched with bullion mountings, and the whole work is such as reflects great credit on the manufacturer.

AN IRON TORCH.—The *Iron Age* says: "The combustion of iron in air is a chemical phenomenon now made comparatively easy to the experimenter. The most practicable method is to take a straight bar magnet of some power, and sprinkle iron filings on one of its poles. These filings arrange themselves in accordance with the lines of magnetic force, and, however closely they may appear to be placed, of course no two of the metallic filaments are parallel, and consequently a certain portion of air is enclosed as in a metallic sponge. The flame of any ordinary spirit lamp or gas burner readily ignites the finely divided iron, and continues to burn most brilliantly for a considerable length of time, the combustion being apparently as natural and easy as that of any ordinary substance, and the light normal, though vivid."

CAR WHEELS.—The *Railroad Gazette* says: Forty-two inch cast iron car wheels, we learn, are now being tested by several railroad companies. The Atchison, Topeka & Santa Fe, the Flint & Pere Marquette, the Grand Trunk roads are running a few sets each, and the Lake Shore & Michigan Southern have recently ordered several sets to test. The Pullman Company has for some time been running wheels of this size, some made of cast iron and some "paper" wheels with steel tires.

TO MAKE LEECHES BITE.—*Le Progres Medical* advises, in order to make a leech bite readily, to place it in a glass containing cold water, to wash the skin of the patient with warm water, and apply the glass containing the leech at once.

DEWEY & CO.

American & Foreign Patent Agents

OFFICE, 224 SANSOME STREET, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent Reissues taken out; Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Baden, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Granada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established. Our schedule price for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) sooner than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more correctly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing to them the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

DEWEY & CO.,

United States and Foreign Patent Agents, publishers Mining and Scientific Press and the Pacific Rural Press, 224 Sansome St., S. F.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS OFFICE, S. F.

BY GUIDO KUSTEL,
MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their Respective Metals without Quick- silver, 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in his specialty.

Price \$2.50 coin, or \$3 currency, postage free.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arsenurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams, 1867.

This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. PRICE REDUCED TO \$6.

ISSUED OCT. 1st, 1876.

Testing and Working Silver Ores.

The above is the title of an illustrated work of 114 pages, for miners and prospectors by Ohas. H. Aaron, which has just been issued by Dewey & Co. Mr. Aaron has managed to give many useful hints and suggestions, free from all technicalities, and in such a style as to be easily comprehended. It is written for the miner, with no chemical symbols or metallurgical technicalities to confuse those who are not chemists or metallurgists. The following summary of the contents of the work will give an idea of its scope:

Under the heading of the first chapter, "Testing Ores for Silver," we find paragraphs on ore formation, test for silver, with heat and water, acid or blow pipe. In speaking of testing for a process, the extent and richness of ore is considered, smelting ores, selecting and working sample, appliances for testing, roasting, etc. Under the head of "Working Ores" the author describes Aaron's process, has something to say of superheated steam, preparation of dichloride of copper and protodichloride of copper, use of copper and iron, quantity of chemicals, carbonate of lime, chloride ores, amalgam, Patchen's process, etc. He also describes the methods of working roasted ores, treatment of base metals stirring, heat of furnace, want of sulphur, etc. Under the head of "Leaching Processes" are the titles, Smelting, Mexican process, Koenig's process, Chilean process, etc. Under "Pulverizing Machines" are described the arastra and its construction and operation, stamp batteries, screens, Crocker's trip-hammer battery, Paul's pulverizing barrel, Kendall's battery, Nolce's pulverizer, a cheap rock breaker, etc.

In speaking of amalgamators the author describes a cheap amalgamator, grinding the ore, directions for making a barrel, preventing mechanical wear, use of quicksilver, copper in bars, Freiberg barrel, cheap barrel, trough, barrel on rollers, Aaron's amalgamator, separator, etc.

He describes an improved retort, roasting furnace, furnace tools and furnace building. Among the miscellaneous mention may be found Aaron's leaching apparatus, with two or three different arrangements, a small mill, sampling tallies and setting tanks, dichloride of copper, etc. Mr. Aaron is a practical miner, of long working experience on his coast.

The book is a serviceable one for miners' and prospectors' use. Price, post free, (in leather,) \$2.00. Address Dewey & Co., MINING AND SCIENTIFIC PRESS, 224 Sansome street, San Francisco.

The Explorers', Miners' and Metallurgists' Companion.

Comprising a Practical Exposition of the Various Departments of Exploration,

Mining, Engineering, Assaying,
and Metallurgy,

Containing 672 Pages and 83 Engravings

BY J. S. PHILLIPS, M. E.,

Of California, a Practical Operator for Thirty-four Years; Explorer, and Resident in the Pacific States and Territories for the past Eight Years.

PRICE, bound in cloth, \$10.50; in leather, \$12. Forwarded by mail for 50c. extra, at the MINING AND SCIENTIFIC PRESS OFFICE, by

Dewey's new elastic fileholders (black walnut), size of the Press, Harper's Weekly and Scientific American, for 50 cts. Larger sizes, to suit any newspaper, 75 cts. By mail, postpaid, 10 cts. extra. Cash with all orders. Patent allowed. Address, Dewey & Co., Publishers, San Francisco.

Mining and Scientific Press.

Is the leading mining journal in America, and enjoys a large circulation among the more intelligent operators and workers in the gold fields of the world.

As a scientific and mechanical representative of the Pacific Coast, it is decidedly popular and a standard journal with the most thrifty industrial people of the Pacific States and Territories. Its authority is of the highest order, and its usefulness in its special sphere unrivalled.

Every public library, mining engineer, metallurgist, mining operator and intelligent mechanic and manufacturer will find profit by its reading.

Subscription, \$1 a year, in advance. Sample copies post paid, 10 cents. As an

Continued from page 9.

before. The first and most efficient parties in bringing about this union of forces were the large companies, who, though not yet sued and abundantly able to take care of themselves should they be assailed, generously undertook the defense of their weaker brethren who had already been attacked, and who, with their limited means, might not have been able to cope successfully with the powerful combination arrayed against them.

This association is composed wholly of companies and persons owning or interested in the various branches of gold mining in California, or in water-ditches, tail-slucies and other properties auxiliary or appurtenant to some department of this business. Already its memberships comprise all the more important companies in the State, the actual value of the property represented thereby amounting, at a fair estimate, to not less than twenty-five or thirty millions of dollars, which sum, it is highly probable, will in the end be increased to the extent of ten or fifteen millions more. The main purpose of this association will be to defend all suits brought against any of its members wherein any question of general interest or principle of common application is involved, they employing counsel and defraying all the costs attending such litigation to its issue in the tribunals of final resort, should not a satisfactory result be sooner reached. Among secondary objects will be the cultivation of friendly relations between the members, and the general advancement of this branch of mining; to which end a commodious office to serve for the transaction of business and as a place of common resort, will be maintained at a convenient locality in the city of San Francisco, it being the intention of the founders to make this a permanent and actively useful institution.

The Legal Questions and Equities of The Case.

As regards the merits as well as the questions of law involved, there is, of course, something to be said on both sides of this controversy. It certainly seems a great hardship that so much of these lands, which the present owners have bought from the Government and afterwards improved, should be rendered worthless or even have their value temporarily impaired, through the causes complained of. The injury already done is considerable, and if the flow of these tailings is suffered to go on without diversion or abatement, large additional portions of these valuable bottoms must hereafter be invaded and, for a time at least, be rendered unfit for cultivation; and the fact that this destructive process is liable to be at any time greatly accelerated by one of those winter floods that periodically occur in these mountain creeks and rivers, is one that should not be lost sight of. It is a fundamental principle of law, say these farmers, that every man shall be required to so use his property as not to cause injury or annoyance to his neighbor, and that for every intentional injury done the law provides a remedy. The injury in this instance being palpable and unquestioned, these good people are now anxious to see the remedial clause of this legal maxim practically tested. To this sort of argument

The Miners Reply:

We too have bought our lands from the General Government, paying double prices therefor under the implied assurance that we should be permitted to go on and utilize them in the manner we had been accustomed to do; our occupation and subsequent purchase thereof having long ante-dated that of the farmers, while our improvements have cost a hundredfold more than theirs. We entered upon these lands with the consent and approval of the Government nearly thirty years ago, and then and there commenced this business of gold mining, building it up and establishing it by such rules and regulations as our hard necessities suggested and our protection required; which local rules, through general adoption and long use, came at last to be recognized everywhere as law, the courts being governed by them, while Congress and the State Legislature declared that they should have the full force and authority of statutory enactments. Among these local rules, so received and engrafted upon our general code of laws, was one providing that the hydraulic miners might introduce foreign water upon their claims for the purpose of washing, and there discharge the same, allowing it to flow thence into the adjacent rivers and canyons, regardless as to what might become of it afterward. Many years after these local regulations had, through prescription, so gained universal recognition and the force of law, and in some instances even after they had received the sanction of the highest authorities, legislative and judicial, these farmers, although there was then still plenty of public land elsewhere upon which to settle, came and planted themselves right in the path of this outflowing sediment, being at the time well advised as to the existence of these usages, and the danger to which they were thus exposing themselves. They acted with their eyes open; acted with a full knowledge of the rights of the miners, the decisions of the courts, and the declarations of the Government, as well as of the manner in which this sand, gravel and sediment had already begun to lodge along these several outlets, and was likely thereafter to accumulate to a damaging extent, and that having so acted, with a knowledge of all these facts, they should not now complain, much less appeal to the tribunals of the country for relief against a trouble that they heedlessly brought upon themselves. Moreover, it is contended by the miners that this vexatious and hurtful material might easily have been converted from an agent of annoyance

and harm into one of fertility and wealth, had these thriftless husbandmen adopted timely means for distributing it over their lands, instead of suffering it to accumulate in undue quantities along the margins of the streams. These tailings, by the time they have reached the lower valleys, where the most of these alluvial lands are situated, consist of a mere silt, or at most a finely comminuted sand, all the large stones, gravel and coarser sand being left behind the boulders in the mining pits, and the balance of this stuff in the beds and along the banks of the canyons and streams above. The water, when it arrives in the vicinity of these bottom lands, being charged with this fine sediment and warmed by the sun, is in a condition highly favorable for use both as an irrigator and fertilizer of the soil, to which purposes it might in all cases be applied with great advantage.

Disastrous Effects of Closing the Mines.

The foregoing, while they cover the leading points, do not by any means embrace all the arguments employed by the miners in defense of their cause. It is urged, for example, that to stop this branch of gold mining, which is now turning out some twelve to fifteen million dollars per year, would, at this juncture, be likely to greatly embarrass the General Government, and possibly inflict serious injury upon our credit abroad; the great want of the Federal Treasury, and, indeed, of the entire financial world, being just now a fuller supply of this class of the precious metals; again, the destruction of this business would fall with crushing effect upon many other industries and callings in the State, to say nothing of the ruin that must thereby be entailed upon that large and enterprising class of citizens who, relying upon the rulings of the courts and the pledged faith of the nation, have invested so many millions in these hydraulic mines, ditches, reservoirs and other works subsidiary thereto. In this entire class of improvements there have been expended, first and last, not less than fifty millions of dollars in this State, and this not including expenditures made on account of enterprises carried out and ended, or those dead and profitless works, of which we have had so many in our day. Upon what is known as the San Juan divide, being the high ridge lying between the South and the Middle forks of the Yuba, there has been expended on and about what may be considered live enterprises, purchases and improvements all included, fully twenty million dollars, all of which with the stoppage of hydraulic washing would be extinguished at a blow. To arrest this industry, even in that one locality, would be to throw thousands of well-paid laborers out of employment, dry up vast and costly ditches and reservoirs, blot out of existence populous and thrifty towns, as if swept by fire, and in short, restore this entire district to its original solitude and desolation, no other style of mining being here largely prosecuted, and the other natural resources of the country being of limited extent.

This divide has been estimated by the U. S. Commissioner of Statistics to contain 1,820,000 cubic yards of auriferous gravel, which, at the lowest calculation, will yield, under hydraulic treatment, 30 cents per cubic yard, making the value of the gold here contained \$546,000,000—a sum which can only be extracted by the hydraulic method of washing, and which it is not to be supposed either our Government or our people will consent shall be lost to commerce and the world because of the comparatively trifling damage that would, by the process of its extraction, be inflicted upon the farming lands below. And this is but one of the many localities, almost equally important, that might be instanced in California. Such, then, are some of the arguments upon which the hydraulic miners will rely to defeat the suits instituted against them, and to justify themselves in continuing and extending still further this class of operations.

Legal Foes but Personal Friends.

It is proper to observe that notwithstanding their clashing views and interests, very little ill feeling has been manifested by the parties to this contest, which has thus far been carried on in a conciliatory, and we might almost say, friendly spirit. Each is aware that the other possesses rights in the premises that are entitled to consideration and respect, both being alike anxious for an early adjustment of their difficulties through legislative or other peaceful instrumentalities if possible and through the intervention of the courts if necessary. No intemperate charges have been made nor acrimonious spirit indulged in, nor can it be said that either party has, during the progress of this contest, shown a disposition to prejudice the claims or otherwise secure any undue advantage over its rival. So good an understanding has indeed been maintained between these two classes, that several of the larger mine owners are even now assisting the farmers of Linda township, Yuba county, in the construction of an extensive and costly levee, whereby many thousand acres of bottom land along the lower Yuba will be protected from threatened overflow, the voluntary contributions of these considerate and large hearted men in aid of this work amounting to some fifteen or twenty thousand dollars. Outside this legal fight friendly relations and the most cordial good will are, and no doubt will continue to be, cherished between the contestants, who, it is to be hoped, will yet be able to meet upon some common ground and through their joint influence and efforts procure such legislation as will admit of their differences being settled and disposed of without the intervention of the courts.

To put an entire stop to this branch of min-

ing is out of the question. In the discussion of this matter, that much may safely be assumed. To hold the hydraulic miners answerable to the extent that each contributes towards the damage done, even if just, would hardly be practicable. If attempted, this plan would lead to such an amount of litigation and strife as would necessitate its early abandonment. This question must be settled, not by recourse to temporary shifts and expedients, but upon a broad and permanent basis, and in a manner that will take it out of the province of endless and costly contention, the welfare of the Government and the community at large being consulted as well as that of the parties more immediately interested.

A Feasible Way Out of these Difficulties.

Now, fortunately, a solution of this problem, in accordance with the views above expressed, is by the best authorities deemed altogether feasible. Situate along the main arteries of our river system are vast tracts of tule swamps, upon which this debris from the hydraulic mines can readily be conducted, and in the reclamation and improvement of which it would be of inestimable value. Large portions of these marshes, even at low tide, are covered with water, and cannot therefore be drained by means of ditching, nor can the water be wholly excluded from them by levees, owing to the loose and porous nature of the soil. To effectually protect them from overflow and seepage they will have to be so filled in as to raise the entire surface above high tide level. The mass of this soil being made up of tule roots, covered with a layer of decomposed vegetable matter there will have to be added to it some material suited to give it body and substance before it can be successfully cultivated. The only means by which these several ends can be accomplished will be by running upon these swamps this muddy water from the mines, and there retaining it until it has deposited the bulk of its impacting and fertilizing freight. When recovered in this manner these will be much the most valuable lands in the State, selling for prices that would greatly exceed the cost of their reclamation. At the present time, when we are threatened with one of those disastrous drouths which at irregular intervals may be expected to occur in California, cutting short the cereal crops, drying up the grass and decimating our flocks and herds, the great value of these tule lands becomes strikingly apparent. Improved in the manner indicated, these now worthless swamps would afford millions of acres of luxuriant, self-renewing pasture, through the aid of which this immense destruction of property in seasons of drouth might be almost wholly averted. While so much would in this manner be saved, two of our most important and perplexing industrial problems would, through the adoption of the policy here recommended, find a satisfactory solution: a receptacle being provided for the hydraulic sediment, and the vast expanse of tule swamps, now the breeders of mosquitoes and malaria, would be converted into the garden lands of the world. Let, then, the farmers and the miners, instead of wasting their time and money in a strife that can in no event be determined for years, unite their strength and procure such legislation to be taken as will inaugurate this reclamationary work with the least possible delay. If the State Legislature is not competent to deal with the subject in all its aspects, then let their action be supplemented by such congressional or departmental measures as its effectual treatment may call for.

The Ashtabula Disaster.

Details of a terrible railroad accident which occurred this week at Ashtabula, on the Lake Shore railroad, have been received by telegraph. It is now known that about two out of every three passengers were killed.

The disaster occurred shortly before eight o'clock. It was the wildest winter night of the year. The train was moving at a speed of less than ten miles an hour. The head-lamp threw but a short, dim flash of light in front, so thick was the air with the driving snow. The train crept across the bridge. The leading engine had reached the solid ground beyond, and its driver had just given it steam, when something in the under-gearing of the bridge snapped. For an instant there was a confused cracking of beams and girders, ending with a tremendous crash as the whole train, all but the leading engine, broke through the frame-work and fell in a heap of crushed and splintered ruins at the bottom. Notwithstanding the wind and storm, the crash was heard by people half a mile away. For a moment there was silence; then arose the cries of the maimed and suffering.

Those who were unhurt hastened to escape from the shattered cars. They crawled out of the windows into the freezing water, waist deep. Men, women and children, with limbs broken, bruised and pinched between timbers, and transfixed by jagged splinters, begged with their last breath for aid that no human power could give. Five minutes after the train fell a fire broke out in the cars piled against the abutments at the other end. A moment later the flames broke from the smoking car, and the first coach piled across the other, near the middle of the stream, less than 10 minutes after the catastrophe. Every car in the wreck was on fire, and the flames, fed by the dry varnished work, licked up the ruins as though they had been tinder. Men, who in the bewilderment of the

shock sprang out and reached the solid ice, went back after the wives and children and found them suffocating and roasting in the flames. People living in the neighborhood were startled by the crash, and lighted to the scene by the conflagration, which made even their prompt assistance too late. By midnight the cremation was completed. The storm had subsided, but the wind blew fiercely, and the cold was even more intense.

The iron bridge structure was a single span of 159 feet, crossed by a double track, and was 70 feet above the water. The descent into the valley on either side is precipitous, and as the hill slopes are piled with heavy drifts of snow there was no little difficulty in reaching the wreck after the disaster became known. The bridge has been regarded as one of the very best of the kind in the country. It has been tried with six locomotives, and trains frequently crossed on both tracks simultaneously without causing more than a slight deflection of the structure. It is conceded, however, that the continued impact of heavy trains crossing these iron structures destroys in a measure the integrity of the iron or crystallizes it in such a manner as to weaken it; and in this case the extreme cold probably had a serious effect. The accident is one of the worst which ever occurred in the United States, but will have the effect no doubt of causing a minute and scientific examination of the railroad bridges all over the country, as the Brooklyn disaster called the attention of the police to the condition of theaters.

Too much care cannot be taken or too much caution exercised in building and keeping in repair structures on the strength of which so many lives depend, and a careful examination of the causes of this disaster may develop facts which will be of a protective nature to the traveling public. As the bridge fell the driver of the locomotive in front gave it a quick head of steam, which tore the draw-head from its tender, and the liberated engine shot forward and buried itself in the snow. The other locomotive, drawn backward by the falling train, tumbled over the pier and fell bottom upward on the express car next behind.

General News Items.

The Grand Duke Nicholas is convalescent.

The Lykens Valley colliery, near Pottsville, Pa., is on fire.

The railway operators' strike in Canada still continues.

GENERAL CROOK's campaign against the Indians has closed.

EPH. HORN, the celebrated minstrel, died in New York on Wednesday.

EIGHTY THREE AND THREE-TENTHS of the predictions of the Signal Service Bureau have been verified this year.

The debt statement shows an increase during December of \$358,142; coin balance, \$95,517,418; currency, \$9,483,860.

The Government subsidy of the Pacific Mail Steamship Company for carrying the mails to China and Japan expired with the year.

The German government has ordered the Imperial bank of Germany to resume the sale of silver for account of the German treasury.

The Sutter Street wire-rope railroad commenced running on Monday, to comply with the law, and the trial was found to be satisfactory. The road will be in operation for the transportation of passengers in about two weeks.

PROMPT PAYMENT OF LOSSES.—The prompt payment of losses by insurance companies is ever considered, by insurers, a most encouraging feature in their management. In this respect we believe the Farmers' Mutual Fire Insurance Association of this city is particularly noted thus far in its history. Our attention has just been called to another instance of promptness in that company, wherein, as we learn from a "card," published by G. W. Hoag, of Jacinto, that within five days of the date on which his dwelling was destroyed by fire, Mr. J. D. Blanchard, president of the company, visited the premises, adjusted the claims, and paid \$5,000, the amount of the policy. Such instances of unusual promptness are well worthy of notice, especially when so many in all branches of business are taking advantage of every possible technicality to avoid payment of really honest dues.

PICKERING ENGINE GOVERNOR.

Vallejo Foundry, October 17th, 1876.
Messrs. NEYLAN & YOUNG, San Francisco,
Agents "Pickering Governors."

Gents:—The 10 two-inch Improved Speed Adjusting Governors I bought of you this year for my patent Straw Burning Threshing Engines give splendid satisfaction. They far surpass for regularity of speed any Governor that I have ever seen, and I have seen all the best kinds; I have seen the main belt fly off the pulley several times this season while threshing, and the engineer did not discover it, so perfectly was the speed maintained, until he was told of it; this I consider something wonderful; I consider the Governor absolutely perfect, so far as speed is concerned. I bought and put on to one of my engines a Shive Governor, to see which was the best, and after one season's trial I have no hesitation in saying they are far superior to the Shive or any other Governor that I have seen or used, as the Shive Governor is to the old Butterfly Valve Governor. I wish you would send me the lowest price that you can furnish 25 Governors for next season's engines.

Yours respectfully,
I. L. HEALD.

For Mining and Other Purposes.

Steam Engines and all Kinds of Mill and Mining Machinery.

THE O'HARRA
CHLORIDIZING FURNACE

Guaranteed to Chloridize from 85 to 95 per cent. of any gold or silver ores that are not more profitable for smelting. Will also desulphurize ores and put them in proper shape for working in cupola furnaces.

Cost of Roasting and Chloridizing by this Process:

Two cords of wood at \$6.....	\$12.00
Two firemen at \$4.....	8.00
1,500 lbs of salt at 15c.....	22.50
Wear of shoes and power.....	1.50

Cost for 15 tons.....	\$44.00
Cost for one ton.....	2.93

In a furnace of three or four times this capacity the cost is decreased by 20 per cent.

The furnace is now working successfully at the Poe Consolidated Co.'s mines, in the Peavine District. For further information, apply to

D. J. O'HARRA,
Reno, Nevada.

The Great Western Scroll Saw Co.'s new and improved \$5.00 Foot and Steam Power Scroll and Bracket Saw is the best one yet invented. With it men and boys are making from \$3 to \$10 per day. We will send you a Machine, six Saws, 15 Patterns and two feet of prepared wood, on receipt of \$5. Address,

Appreciative.

DEWEY & Co., San Francisco—

Gentlemen:—My patents for the Eclipse Baling Press and for my Improved Excavator have both come safely to hand. They are entirely satisfactory in all respects, and in my judgment, fully and clearly cover all the points to which I am entitled. I thank you earnestly and sincerely for the care and dispatch you have used in both cases, but wish to acknowledge my special obligations for the patient persistence with which you pushed my claims on the excavator, in the face of the various adverse decisions of the examiner. When you advised me to appeal on a certain claim, I had grave doubts of the advisability of the proceeding, but the result justified your judgment, and I was as much surprised as gratified when I received notice from you that the examiner had receded from his position in the matter, and that the money that I had advanced to prosecute the appeal was not needed, but awaited my order. I will add also that I had some misgivings as to the cost of patents obtained through your agency when compared with Eastern solicitors, but am glad to acknowledge that my cases have been as cheaply prosecuted by you as by parties East, to say nothing of the advantage of personal conference as to claims and the saving in point of time. I have two more models nearly ready for you. Yours respectfully,
JACOB PRUGE.

E. SCHULTZE,
MANAGER.

DEWEY & CO.,
Publishers and Patent Agents.

The Large Circulation of the Mining and Scientific Press extends throughout the mining districts of California, Nevada, Utah, Colorado, Arizona, Idaho, Montana, British Columbia and to other parts of North and South America. Established in 1860, it has long been the leading Mining Journal of the Continent, its varied and reliable contents giving it a character popular with both its reading and advertising patrons.

SAN BERNARDINO, Cal., Sept 29th, 1876.

MESSES. DEWEY & CO., S. F.—
Gentlemen:—I was very much pleased a few days ago to receive my patent in the "Pastry Bureau" case, and I take great pleasure in recommending your agency to those who may have business in that line, particularly the first time. The courteous, prompt and efficient manner in which you act as patent solicitors is certainly the highest recommendation an inventor could ask; and to this fact I am pleased to attest. Hoping that our mutual interests have not ended with this successful issue, for I shall need your services in future, I remain truly yours,
J. B. FELZER.

THOUGHTLESSNESS.—Persons sometimes return their paper, marked "stop this paper." Their name being pasted on the sheet they think that is all we need to be able to cross their names off. Now that is thoughtlessness. Your P. O. address is needed as much as your name. We have thousands of names arranged only according to locality. Our mailing clerk does not know where everybody lives.

BOUND VOLUMES OF THE MINING AND SCIENTIFIC PRESS from Jan. 1st, 1874, are for sale at this office at \$5 per volume, two volumes a year. Unbound at \$3 per volume.

Some Reasons for Subscribing for It.

Because it is a permanent, first-class, conscientious, able, and well conducted journal.

Because it is the largest and best agricultural weekly west of the Rocky Mountains.

That more farmers' wives and children in their isolated homes may be cheered by its weekly visits, laden with its pleasing yet moral reading, and sound instruction.

That a more extended interchange of views and opinions may be had among farmers, upon all the great questions touching their mutual interests and progress.

That the agricultural resources of the Pacific States may be more wisely, speedily and thoroughly developed by an open and free discussion in our columns.

That all the honest industries of our State may be advanced in connection with that of agriculture, our columns being ever open to the discussion of the merits of all progressive improvements.

That the Rural, after having been read and pondered over by the home circle, can be filed away for future useful reference, or forwarded to the old Eastern fireside of the Atlantic border, in aid of an increasing immigration to our sunny clime.

Subscription, \$4 a year in advance.

Improved Concentrating Tables.

The illustration on this page represents an improvement in concentrating tables for ores, recently patented through the MINING AND SCIENTIFIC PRESS Patent Agency, by J. U. Tolles, who has been using the apparatus successfully in several places. In the engraving *A* represents a flat inclined table, provided with a surfacing of cloth of any suitable kind, and with ledges, *b*, to prevent the material from passing over the ends. *B* represents a feed box extending along the upper edge of the table, and provided in its front side with a row of discharge openings, *c*, of the form shown, each narrowing down to a point at its lower end. *C* represents a receiving trough or box extending along below the lower edge of the table. *D* represents a leaf or board hinged to the rear side of the trough or box *C*, in such a manner that it may be turned under the edge of the table, to conduct the material therefrom into the box, so that the material passing over the edge of the table will be discharged outside of the box. *E* represents a rotating tube suspended lengthwise above the upper edge of the table by endless belts, *d*, passing over pulleys, *e*, supported in the rigid frame. *F*. The tube is provided from end to end with a row of perforations, and with a hand lever, *h*, at one end, and is connected by a hose, *i*, and a reservoir or pump delivering water at a pressure corresponding to a head of from eight to twelve feet.

In operating the machine the feed box, *B*, is partly filled with rough stones, to insure an even distribution and a steady flow of the material to be treated, a steady and copious supply of water maintained in the box, and the ore, sand or tailings introduced therein. The water, escaping through the openings, *c*, flows down in a thin film or stream over the face of the table holding the material in suspension. The heavy and valuable particles are deposited upon, and retained by, the cloth surface of the table, while the light refuse particles are carried over the lower edge and discharged outside of the box *C*. After the collection of a suitable amount of metal upon the table, the supply of water to the feed box is stopped, the leaf *D* turned under the edge of the table, and water supplied to the pipe or tube *E*, by which it is delivered through the perforations upon the table in a row of fine jets, forming an almost continuous sheet or film.

By means of the lever, *h*, the tube, *E*, it is rotated and the sheet of water swept over the table from top to bottom, so as to drive all adhering particles therefrom, and wash them down into the collecting box, *C*. After this operation, these jets are stopped, the leaf turned out, and the feed water again started. By employing the cloth surface, giving the table the proper inclination and properly regulating the flow of water, the inventor finds that he can effect a rapid and thorough separation without agitating the table, and without the employment of manual labor for any other purpose than that of feeding the material; and by the employment of the fixed table, with its cloth surface, he can separate particles which cannot be retained in machines which vibrate. By the use of the feed openings, *c*, of the form shown,

the discharge of the sand, ore, or other fine material is rendered very steady and gradual, as it will be carried through the narrow portion of the openings, while the lighter water will pass over the same, through the upper large end of the openings, taking up the material gradually and distributing it evenly upon the table. It is obvious that the rotating tube may be sustained in any other suitable manner, and that it may be connected in any suitable manner with the source of water supply.

The object in arranging the perforated pipe so that it can rotate is to permit a gradual change in the direction of the jets, so that their point of impact upon the table can be advanced from its upper to its lower edge and thereby every portion of the surface subjected in turn to the direct impact of the jets in order to effectually loosen and drive forward the particles therefrom.

The flow of water can be regulated by the valves operated by the cords. The gate shown in the feed-trough *g*, will throw the

Items of Interest from the Mines.

We give below items of interest from prominent mines, most of which are collated from letters of the respective superintendents on file at the offices in this city. Considerable of this news is later than that procured from the interior journals:

They have put a Blake pump in the 2,000-foot level of the Con. Imperial mine, which will throw to the pump on the 1900-foot level about all the water there is in the mine.

In the Justice a connection has been made with the 400-foot level winze and the 500-foot level upraise, which furnishes a valuable ore slope 125 feet in height.

The last clean-up of the Eureka (Grass Valley) mine was 205 ounces of amalgam.

The last letter from the Raymond & Ely mine says: "The raise which was being carried up from the west drift on the 11th level has been

Portable Engines.

Messrs. Baker & Hamilton, of 15 and 19 Front street, in this city, are agents for a number of different varieties of small and portable steam engines, adapted for all classes of work. Of late they have made a specialty of this class of machinery, and have the largest variety in the market. The Bigelow portable engine we described in detail some time ago. It is built for a low-priced portable engine, having no bright and polished work, but is of unexcelled workmanship. These engines are made 50 at a time, so as to be made cheap, and are fitted complete, ready for running, except the smoke-stack. The boilers are built on the most approved plan and from the best iron. These engines are made from four up to 15-horse power, and are fixed up and tested before being put on the market.

The Baxter portable steam engine, manufactured by the Colts Arms Company, is so well-known as to need no description. It has no special novelties, but is a steam engine and boiler, plain and simple. It is largely in use all over the United States in all branches of business in which a small motor is desirable.

The Bookwalter engine is intended for processes requiring light power and is especially adapted for those purposes. The manufacturers confine themselves only to two sizes. All parts are made in duplicate. The engine, bed plates, pump, governor, etc., are made and attached to the boiler in the most simple and firm manner, so that the heat from the boiler does not by expansion change the relations of the working parts to each other. Every boiler and engine is tested by hydraulic pressure to twice the working pressure and is in perfect working order when sold. These engines are furnished at a low price.

The "Hero" vertical engine and boiler is a new style of semi-portable, both efficient and durable, economical in fuel as well as in space occupied and is thoroughly constructed and serviceable. The base or foundation is perfectly tight and secure, making it as safe as an ordinary stove. Two sizes are made and the engine and boiler are furnished complete with governor, safety valve, pumps, gauges, etc.

The portable engines made by the Ames Iron Works are made in various styles and are principally known on this coast as in use for threshing engines. The engines are superior in design, workmanship, and material, as well as economical in use of fuel and running expenses. Eleven sizes of these engines are made, from three to forty-horse power. Every piece of these engines is fitted to a standard gauge, and duplicate parts can therefore be procured.

Messrs. Baker & Hamilton are also agents for the Shive governor, of which we shall shortly give illustrations with a detailed description. This governor is made on scientific principles and is highly recommended by those who have used it. The advertisement of Baker & Hamilton will be found in another column.

VULCANITE.—The Supreme Court has rendered a decision in the vulcanite case, in which all the dentists of the country are interested. The rights of the patentee of the vulcanite are sustained by the decision.

TOLLES'S IMPROVED CONCENTRATING TABLES.

water into either feed-trough as desired.

Mr. Tolles, with this apparatus, does not profess to do what many others claim to do, but he is running many of them where everything else has failed. He has been running a good many of these tables on the Comstock for nearly two years and is now building more. Persons at a distance can build and run them, by first obtaining license and instructions of the inventor, John U. Tolles, at Eureka, Humboldt county, California, or W. S. Tolles, his authorized agent at Virginia, Nevada.

THE LICK ESTATE.—It is stated that a compromise has finally been effected between the different relatives of the late James Lick and the trustees of the estate, by which an amicable settlement will be made. The compromise involves the payment of the sum of \$383,000 in addition to the sum of \$150,000, left to John H. Lick, but the two societies who will have to pay this money have yet to be heard from. The residue, after certain specified bequests are paid, goes to the Academy of Sciences and California Pioneers, and as the compromise money comes out of their share, the consent of these societies to the compromise must be gained before the matter is finally settled.

run through and connected with the winze sunk from the 10th level, furnishing a good circulation of air, and we are now engaged in pushing the main drift westward, and a reasonable hope may be entertained that the favorable vein matter found on the west drift on the 10th level may improve as depth is attained, and may possibly develop ore between the end of this drift and the west cross-drift. The water in the main shaft is up within 20 feet of the 11th level, and before the pump is in operation again it will have reached the point where it was first encountered in the shaft."

The chloriders are still operating in the old abandoned levels of the Meadow Valley mine, but the ground has been worked over so often that what little ore there is remaining in the old levels is of rather low grade.

The average assay value of the ore mined at the Chollar last week was \$29.50 per ton.

The rock encountered in the west drift from the 1,650-foot level of the C. & C. shaft is said to be harder than any ever before encountered on the lode.

The ventilation of the Best & Belcher mine has been materially improved by enlarging the main drift on the 1,500-foot level.

The average of the Manhattan ores worked for the past week is \$246.60 per ton, showing an increase of \$30.62 per ton over last week.

Review of the Pig Iron Market.

Messrs. Jeffray & Harrison, metal and coal brokers, have issued the following annual review of the pig iron market of San Francisco for the year ending December 31st, 1876:

The monthly quotations, as given below, will show that soft iron has ruled more uniformly in price during 1876 than for some years past. The heavy stock in importers', jobbers' and foundrymen's hands at the opening of the year, combined with the extremely low rates of freight from the Eastern States, and from England, caused low prices to rule the entire year. Importers, availing themselves of the low rates of freights, sold large quantities "to arrive" at the then ruling low prices. During December our quotations will show a marked advance, caused by a corresponding advance of freights; still our outside prices of spot lots for December are to some extent nominal, few sales having been effected at our extremes. White iron has been more fluctuating during the year than soft, caused by a concentration of the stock on hand early in the season. It was anticipated the consumption this year would have been much greater than the results show, as the foundrymen had large contracts for the first six months; but the last half of the year the consumption has been extremely limited; still the outlook for 1877 is very encouraging for an increased demand. In estimating the amount of stock on hand, we have included all the pig iron in the interior and State of Nevada; also 1,400 tons of Salisbury iron. The following will give the month's quotations for the year 1876:

Month.	Scotch, soft. Per ton.	Am'n white. Per ton.	Am'n soft. Per ton.
January.....	\$31 00/33 25	\$30 00/31 00	\$30 00/31 00

We find the stock of pig iron on hand January 1st, 1877, in all, 15,456 tons, as per statement given below, being 3,906 tons in excess of the stock on hand January 1st, 1876.

	Tons.
Stock of Pig Iron on hand January 1st, 1876.....	11,550
Imports of 1876—Scotch, soft, tons.....	10,704
do do American, soft.....	8,564
do do American, white.....	425
do do English, white.....	2,294
do do French.....	321
do do Oregon.....	1,006—23,225
Total.....	34,775

DETAILED ACCOUNT OF STOCK ON HAND JANUARY 1ST, 1877.	
Importers' hands, Scotch.....	4,900
do do American, soft.....	1,870
do do White.....	180—7,110
Foundrymen's and Jobbers' hands, Scotch, soft.....	2,915
Foundrymen's and Jobbers' hands, American, soft.....	3,796
Foundrymen's and Jobbers' hands, white.....	1,755—8,446
Total.....	15,456

Consumption of 1876, white.	
do do American, soft.....	5,983
do do Scotch, soft.....	10,510—16,493
On the way, as per latest dates received:	
From Scotland and England.....	2,476
From United States.....	1,643—1,419
Stock on hand.....	15,456
Total.....	19,575

The above figures show an increased consumption this year over last of 1,439 tons, viz.: 206 tons of soft, and 1,233 tons of white. The importations of 1876 show a decrease of 4,821 tons as against the importations of 1875.

The Salinas Quicksilver Mine.

We continue to receive the most encouraging reports from the Salinas quicksilver mine, all of which is very gratifying, as several of our citizens are largely interested in the property. The tunnel is now in 230 feet, 139 feet of which distance from the face backward towards the mouth is on a fine body of metal. At a point 166 feet from the mouth of the tunnel an incline shaft is being sunk on the lode, which dips at an angle of about 45 degrees. This incline is now down 40 feet, at the bottom of which the vein is four feet in width, with eighteen inches of solid metal and steadily improving as they go down. The face of the tunnel is 170 feet below the surface, the entire depth being a well defined vein of antimony and quicksilver—at least such is thought to be the case, as it shows well both on the surface and in the face of the tunnel.

Sixty per cent. ore is worth \$50 per ton delivered in San Francisco, and this is the kind being shipped by the company at present. After paying all expenses it leaves a profit of about \$35 per ton. From the mine to Hollister, the shipping point, there is a good mountain road, over which four animals can without difficulty haul 3,500 pounds of ore.

As soon as the mine is properly opened they will commence stopping out the ore on an extensive scale. It is estimated that there is at least

\$30,000 worth of ore in sight, besides which they have 100 tons of 20 to 60 per cent. ore on the dump, which will be smelted as soon as the company get their own furnaces in operation, for which they are now cutting the wood to burn the brick, which will be manufactured on the ground at a saving of \$20 per thousand in the price of them.

Superintendent Shriver has erected seven new buildings at the mine this fall—a blacksmith shop, three dwellings, barn and stable, lodging house for the men, and a store-room.

In addition to the mine which they are working, the company own 235 acres of mineral bearing ground in the immediate vicinity, on which there is an abundance of wood growing, which can be utilized as fuel to run the furnaces and as timber for the mines.

There are 40,000 shares in the incorporation, owned principally by men who intend to develop the property, and are confident they have a good thing. A few months ago the stock was selling at \$1 per share, but on the strength of recent development, it has now gone up to \$3.83, some having been sold at the latter price a few days ago.—*Salinas Index.*

A Rich Country.

The pressing want of the people of the country to-day is more gold. Political matters are badly muddled, and everybody is interested to know what will be the outcome, but how to get coin is a subject of more vital importance to every one than who is to be President. We can all live whether Hayes or Tilden controls the helm of State if we have plenty of money. How and where to get it is, therefore, the question of paramount importance, and the one which we propose to answer in this article. The surest way to get gold is to go where it exists in large quantities and dig it out. The place where it can be found is almost anywhere in Nevada county. At present, developments which are being made on the upper part of the San Juan ridge, show that that section contains the precious treasure in almost unlimited quantities. We have obtained some information from Surveyor Fen Miller, who has, during the past two years, been running lines in that vicinity, which we propose giving to our readers. It has long been known that the Blue Lead, or ancient river channel, in Sierra county, crossed the Yuba river and run over into Nevada county and along down the San Juan ridge. The channel leaves Sierra county at a point near Minnesota, and is again discovered on this side the river in Nevada county at Snow Point. Mr. Miller has surveyed on the supposed line of it from Minnesota down to North Bloomfield. The natural descent of the channel for that distance is 190 feet to the mile. It falls from Woolsey's Flat to Malakoff about 1,000 feet.

The gravel and the character of the gold in the lead is the same in both counties, and those familiar with the country have no hesitation whatever in declaring that the two leads are identical. The ground on the line of the channel is laid off and claimed nearly the whole distance to French Corral, over 15 miles. The richness of the lead the whole distance is beyond dispute, as it has been prospected and worked at intervals all along between the two points for years, but recent developments show that even the most sanguine never dreamed of the wealth lying hidden there. Mr. Miller informs us that the claims owned by Cowger & Co., at Snow Point, the first entrance of the channel into Nevada county, are proving to be remarkably rich. For want of water there are but two men employed in the claims at present, but they are taking out all the way from 50 to 80 dollars each per day, and the gravel grows richer as they follow the lead into the hill beyond. This claim was worked in early days, but the owners ran too far to the east and lost the channel. On returning to the old bank on the west side of the claim, some time since, they struck good dirt, and by following it into the hill they have discovered what was always supposed existed there. We are informed by Mr. Miller, that from the pitch of the bed-rock and the direction the channel seems to be running, there is no longer any doubt that the theory of those who have located on the line between the Point and Bloomfield was correct, and that there is between the two places the richest field of gravel in the world.

The North Bloomfield company, after years of labor and the expenditure of over \$2,000,000, have got their claim thoroughly opened and have washed down to bed rock, where they find gravel of surprising richness. The bottom of the channel at that point is over 400 feet in width, and about 350 feet in depth. It prospects astonishingly well, and good judges think the company will in a few years get back all they have expended, and will have but barely opened up the mine for extensive work. These developments at the two points, a distance apart of about seven miles, and the known richness of the Blue Banks, the Boston and other claims at Woolsey's and Moore's Flat, supposed to be feeders, or a part of the same channel, located midway between the two points, prove conclusively the wealth of the whole region, which is as yet but barely touched. To the southwest of the North Bloomfield company, at intervals of a mile or more, clear down to French Corral, extensive and rich paying claims have been opened and are being worked, and are yielding rich returns. Compared with the wealth of this region, the famous Comstock lode of Virginia sinks into insignificance. There is between 15 and 20 miles of this channel yet untouched. It

is a field for the investment of capital not to be found anywhere in the world. The gold does not exist in chimneys as it does in quartz veins, but is evenly distributed the whole distance, and wherever a mine has been opened on the line the developments prove it. The majority of the claims are owned by men of small means who have been, thus far, unable to run tunnels and open a mine, but men of means own some of the claims, and we are informed that the work of developing their property will be started up at once. Each development made on the line of the channel enhances the value of adjoining claims. It is reasonable to suppose that the gold hidden away in the sands of that section will not always be allowed to remain there when it is so badly needed and we anticipate seeing in the future a continued line of paying mines along the whole length of the channel. This is the section where gold in paying quantities exists, and the way to get it is simply to go work for it.—*Nevada Transcript.*

Mining in Arizona.

The main industry of Arizona has always been, still is, and always will be, mining. Although our agricultural and grazing resources are not by any means to be despised, yet their consideration is small when our vast mines of coal, iron, lead, copper, silver and gold are considered. The agricultural and grazing interests of the Territory will be entirely subservient to the mining interest, and the graziers and farmers will always depend on the miners for their support.

Many people are in the habit of thinking that mining is not a permanent industry; that the mines are easily worked out, or at least worked in a few years to a depth beyond which work is impossible—at least unprofitable to work. That this is a fallacy is proved by the mines of Mexico and South America, which have yielded their millions annually for over 300 years, and are still turning out an undiminished supply of bullion.

Mining on the Pacific coast is still in its infancy. Even on the Comstock, where they are now down over 2,000 feet, they are as yet only "scratching among the roots of the sage brush." Hardly a day passes, scarcely a paper comes along, that has not a notice of some new appliance for the better and cheaper working of mines, or the more economical and therefore more profitable reduction of ores, and here in Arizona we can hardly say that we have hitherto done any mining at all. A few "coyote holes" have been dug here and there and a few tons of ore have been shipped or reduced in an astra or rattletrap of a mill, and we are only beginning to realize from the little we have done, what a marvellously rich Territory we have. And meager as the showing in work and yield has been, I will here venture to say that although many thousands have been uselessly and foolishly sunk in Arizona mining, yet more bullion has been shipped out of the Territory than money has been brought into it. I write advisedly.

And if the result has been so encouraging before any real mining has been done, what are we to look for in the future? A short time since nothing was doing. All were waiting for something to turn up. Now in every county in Arizona systematic mining is going on. Complete mills are at work, turning out their thousands daily, and adding in a quiet way to the wealth of the land.

For years Arizona has waited for outside aid—capital, capital, was the cry. At last, tired of waiting, her miners went to work in an humble way, and now the Territory is before the world as a great bullion-producing country and a self-developed one at that. We have to thank no California or Eastern capitalist for our prosperity, but we owe it entirely to the patience, the energy and the industry of the prospector and miner, whose only capital generally consists of dauntless courage and indefatigable industry.

Arizona is in future destined to be the great metal-producing State of the Union. We have not only wonderfully rich mines of gold and silver, but we have apparently exhaustless mines of iron, copper and lead, which in time will not be second in consideration to the mines yielding the precious metals. Patience and a willingness to wait a short time longer and the reward is assured.—*Arizona Citizen.*

Royal Way to Find Rich Mines.

The man with a forked whalebone is operating down at Brown's valley, in Yuba county, and he is showing the people there how to find rich quartz ledges. The people dig where the man with the whalebone points out. That same thing is periodically tried in Grass Valley, but we have never heard of any good mines being discovered by any such agency. We hope the Brown's valleyites will have better luck with that easy way of finding mines than the Grass Valleyites have. The Marysville Appeal tells about the thing in this way:

"Some time ago a singular man named E. Frizell visited that locality, who claimed he could look into the ground and see gold ledges and water leads. He earned the name of 'the Water Witch,' and created some excitement among the credulous. There are two or three companies prospecting for ledges about Brown's valley, who have great faith in the richness of the mines. 'The Water Witch' pointed out the lines to dig upon and some of the miners found ledges as designated by him. In pros-

pecting this man held a small piece of whalebone horizontally from one hand to the other. In one end was placed a small quantity of gold dust, which was covered with buckskin and confined to the end of the whalebone. 'The Water Witch' in passing over the ground with whalebone held in his two hands found that when he reached rich deposits the whalebone would bend in the middle, and often break."

We do not know that the whalebone broke when the man held it in Grass Valley district, but we have heard of one or more companies that were badly broken by digging after the indications of the whalebone. Some people delight to try to cheat hard work and get rich at the same time, but whalebone is not the thing to do it with. It is a singular fact that the whalebone men remain impecunious while having such a key to the secrets of nature. A full kit of miner's tools, well and industriously handled, and with good judgement withal, are the instruments to disclose where the gold is hid in the bowels of the earth.—*Grass Valley Union.*

Mining Outlook in Calaveras.

The Calaveras Chronicle has the following to say of the mining prospects in that county:

The outlook for the mining interests of the county in the future are encouraging and satisfactory, notwithstanding the fact that the progress of development is not so rapid as it could be desired. A fair degree of activity is being displayed in the prosecution of mining enterprises, however, resulting in a steady and healthy growth of the importance of that interest. A notable circumstance connected with this subject is the fact that a greater number of quartz ledges is now being worked in Calaveras than at any time since the inception of that species of mining. Prospecting is also being vigorously prosecuted, which will undoubtedly lead to a steady increase of the number of permanently paying claims. True, operations in some instances result in failures, but in nine cases out of ten the cause is traceable to "financial weakness" or bad management on the part of the owners. The successful development of a quartz ledge requires the employment of capital, as well as a knowledge of the science of mining, and as there are instances where both those requirements are wanting, there is nothing surprising in the fact that there are failures to record. Generally speaking, however, the quartz interests of Calaveras are in better hands to-day than at any period in the past, and operations are assuming that permanent character that augurs well for a better degree of development in the near future. Another noticeable feature of the quartz mining interest is the resumption of work in claims formerly abandoned. Parties relocating claims of that character are enabled to reap the advantage of the labor performed by their previous owners, and very frequently, by the outlay of a small amount of capital in putting up the requisite machinery, develop valuable mines. In a great majority of instances where mines have been abandoned lack of funds to work them properly compelled their desertion, and for that reason relocation is preferable to taking wholly unprospected ledges. Some of the best mines in this county have been obtained in that way, and there are further opportunities of that character yet to be improved. In fact, Calaveras offers better inducements to those wishing to engage in mining pursuits than any other portion of the mineral belt. The county is absolutely covered with a network of ledges, and notwithstanding the great number of claims taken there are yet abundant opportunities for location. Partially or wholly developed mines can be purchased at reasonable figures, if preferred, and in truth any one wishing to engage in quartz operations can suit himself in every particular in this county. It is a knowledge of the superior advantages offered by Calaveras in these respects that is bringing the county into such prominence as a favorite mining locality and giving so great a degree of vitality to operations in quartz. It is clearly evident that Calaveras is rapidly approaching the first place in the ranks of quartz mining counties, and that the importance of that interest is becoming overshadowing.

Gravel mining is a pursuit second in magnitude only to the quartz interest. The hydraulic method of working is almost universally adopted where its employment is practicable, although there are still extensive tunnel claims that cannot be mined by any other method. Gravel mining is really one of the most flourishing industries of the county, and its extent is only limited by the water supply. It has grown rapidly in importance during the past few years, measurably increasing the annual gold product and materially assisting in arresting the decadence that followed the exhaustion of the placers. On the whole we regard the mining outlook as extremely favorable, and the encouraging aspect of that interest is having its legitimate influence in other avenues of business.

A CHINESE TELEGRAPH.—Materials are now on their way out from England for the erection of a line of telegraph from the Imperial Torpedo college, at Tientsin, China, to the Viceroy's Yamen. The line, which will be about five miles in length, to be put up entirely by the students in the college. Once this line is up it is hoped to see telegraphs introduced by the Chinese government, the great objection to their use having hitherto been that foreign engineers had to be employed both for their construction and maintenance.—*Journal of Telegraph.*

MECHANICAL PROGRESS.

New Rock Crusher.

The London Mining Journal says that stone crushers, as at present constructed, are considered by Mr. R. Gardner, of Liverpool, to be complicated and cumbersome; he has, therefore, designed certain improvements with a view to making a machine as simple, strong and compact as possible, combining in the same machine either crushing or breaking. In carrying the invention into practice he makes a very strong iron or steel box or frame, usually forming a parallel-sided rectangular chamber, without top or bottom. Horizontally through two opposite walls of this, through bosses cast sufficiently strong to form bearings, he bores a hole large enough to insert the bearings of the shaft. This shaft is turned eccentric in the middle portion and larger in diameter than at the journals, and the bearings are slid in from the outside after the shaft has been placed in position, and secured with set screws, keys, or other fastenings. In the rectangular chamber, and extending entirely across it, is a movable jaw. This is hinged on the shaft, the eccentric portion passing through it in the hole bored for the purpose, and usually lined with brass. The movable jaw and the side of the rectangular chamber facing it which forms the stationary jaw can be fluted or have projections on indentations cast thereon in any desirable manner. He usually makes these wearing surfaces of separate very strong forgings, or malleable castings of iron or steel, so as to be replaced when worn. The back of the jaw and the side of the rectangular chamber facing it are grooved with a series of horizontal grooves. A stout distance piece or strut of iron or steel has each of its ends so shaped as to fit into one of these grooves. The mode of working is very simple. The shaft being rotated by a strap, or in any convenient manner, the eccentric gives both a vertical and horizontal movement to the top of the jaw, and in front of the distance piece a varying motion depending upon the length and angle of the strut, and direction of rotation. The stuff being inserted between the two jaws by means of a hopper or otherwise, the working of the movable one breaks or grinds the stuff against the stationary jaw. The apparatus will be found applicable to the crushing of slag, chemicals and other substances as well as rocks.

The Swiss Frightened at American Progress.

The speech delivered in the amphitheater of the Primary College of La Chaux-de-Fonds, on the 14th ult., by M. Edouard Favre-Perrot, is a remarkable tribute to American enterprise and ingenuity. M. Favre-Perrot is a Swiss watch manufacturer, who served as a member of the International Jury on Watches at the Centennial, and as one of the Swiss Commissioners to the United States. While in this country he gave careful and intelligent attention to American watches and the methods employed in their manufacture, and he now goes home to tell his countrymen the unwelcome news that vigorous measures are necessary to save the watch-making industry of Europe from ruin. Among other things he said: Had the Philadelphia Exhibition taken place five years later, we should have been totally annihilated without knowing whence or how we received the terrible blow. We have believed ourselves masters of the situation, when we really have been on a volcano. And to-day we must actually struggle if we do not want to encounter in all the markets that rival manufacture. Did we not sneer at Besancon at the outset? And now Besancon suffices for France, and, beside, she exports her surplus of manufacture. We ask ourselves if, in reducing the price of watches, we can increase their sale in the same proportion? And if the sales do not increase, what will become of us? We shall have an enormous stock of goods and a permanent stagnation. The custom duties, you know, amount to 25 per cent. For a long time hopes have been entertained that they might be reduced. We cannot count on it. America needs all her resources, especially in the present situation; and, whether Democrats or Republicans be in power, we cannot hope for a reduction in import duties. We must, therefore, make up our minds to lose the American market!

It has been said, and it has been complacently repeated, that the Americans do not make the entire watch, and that they are dependent upon Switzerland for several parts of the watch. This is a mistake. The Waltham Company make the entire watch—from the first screw to the case and dial. It would even be difficult for them to use our products, so great is the regularity, so minute the precision with which their machines work. They arrive at the regulation of the watch—so to say—without having seen it. When the watch is given to the adjuster the foreman delivers to him the corresponding hair spring, and the watch is regulated. Here is what I have seen, gentlemen! I asked from the director of the Waltham Company a watch of the fifth grade. A large safe was opened before me; at random I took a watch out of it and fastened it to my chain. The director having asked me to let him have the watch for two or three days, so as to observe its motion, I answered: "On the contrary, I persist in wearing it just as it is to obtain an

exact idea of your manufacture." At Paris I set my watch by a regulator on the Boulevard, and on the sixth day I observed that it had varied 32 seconds. And this watch is of the fifth American grade; it costs 75 francs (movement without case). At my arrival at Locle I showed the watch to one of our first adjusters, who asked permission to "take it down"—in other words, to take it to pieces. I, however, wished first to observe it; and here is the result which I noted. Hanging, daily variation one and a half seconds; variation in different positions, from four to eight seconds; in the "heated room" the variation was but very slight. Having thus observed it, I handed the watch to the adjuster, who took it down. After the lapse of a few days he came to me and said, word for word: "I am completely overwhelmed; the result is incredible; one would not find one such watch among 50,000 of our manufacture."

This watch, gentlemen, I repeat to you, I took at hazard—out of a heap, as we say. You understand from this example that the American watch may be preferred to the Swiss. I have finished, gentlemen, and I have told you of things such as I have seen them. It remains for us to profit from this sad experience, and to improve our manufacture. Competent men are not wanting among us; they must go to work at once.

ANOTHER NOTE ON TEMPERING.—The quality of steel should be uniform throughout; indeed, it is always better to have them tempered rather too hard than soft, for use will reduce the temper. If at any time it is necessary to perform the operation yourself, the best method is to melt a sufficient quantity of lead to immerse the cutting part of the tool in. Having previously brightened its surface, plunge it into the melted lead for a few minutes, till it gets sufficiently hot to melt a candle, with which rub its surface; then plunge it in again, and keep it there till the steel assumes a straw color; but be careful not to let it turn blue. When that is the case, take it out, rub it again with tallow, and let it cool. If it should be too soft, wipe the grease off, and repeat the process without the tallow, and when it is sufficiently hot, plunge it into spring water, or water and vinegar mixed. By a proper attention to these directions, and a little practice, every workman will have it in his power to give a proper temper to the tools he may use. If a saw is too hard, it may be tempered by the same means; but as it would be not only expensive, but, in many cases, impossible to do it at home, a plumber's shop may be at hand, where you may repeat the process when they are melting a pot of lead. But here observe that the temper necessary is different to other cutting tools; you must wait till the steel begins to turn blue, which is a temper that will give it more elasticity, and, at the same time, sufficient hardness.—Furniture Trade.

A NEW FIRE ESCAPE.—We read of a new portable, strong, simple and inexpensive apparatus to enable persons to descend or lower others from the windows of the highest dwellings, under complete control and with perfect safety. It consists of a small friction pulley block with four fixed sheaves, having a central movable sheave riveted through slots in the cheeks of the block, to a shackle, having a short chain and ring attached, for the purpose of suspending the block, or weight to be lowered, so that when a person is suspended the weight causes the movable sheave to close on the nearest fixed sheaves, nipping the rope and sustaining the principal portion of the weight. To rescue others the block is hung up by the ring, the person to be lowered is secured by the bag or belt to short end of rope, and the descent controlled as if lowering by an ordinary block, each end of the rope being used alternately until all are lowered. To lower oneself, the short end of the rope is hung up by the ring to the wall hook, the person descending attaches himself by the bag to the ring of the block; his weight causes the block to be drawn down the ropes and he descends as if lowering himself by a simple rope, the block holding the weight and reducing the friction on hands to a minimum. When no wall hook is provided, the apparatus may be securely suspended around both sashes.

PETROLEUM IN METAL WORKING.—Sturtevant's Ingenieur says: The application of petroleum as greasing material in turning on the lathe very hard metals is of great advantage, since cutting tools continually wetted with petroleum may easily attack and work the hardest sorts of steel, which it would be almost impossible to work without the application of this means. It has been shown that a very hard alloy of seven parts of zinc, four parts of copper and one part of tin, which even with the best hardened chisel could not be worked, could be turned with the greatest ease on a lathe, if the tool was moistened with petroleum. With the now more and more frequent use of steel, this discovery is of no mean importance.

AMERICAN WALL PAPER.—The successful exportation of American paper hangings from New York, promises to open up another and profitable line of manufacture. It is found that we can successfully compete with any of the European countries in their own markets in these goods, both in price and quality. Machinery has been applied to the manufacture in this country, while the European manufacturers do the work by hand.

SCIENTIFIC PROGRESS.

Inventors Should Study Science.

At a late engineers' meeting in England, Mr. Alexander Smith read a paper on the need of science in invention. We quote a paragraph: It has been far from an uncommon thing for ingenious and clever men to waste their time and money in trying to discover or accomplish impossibilities which a knowledge of physics or natural philosophy would have entirely prevented. We have read of the search for the philosopher's stone, and later on of perpetual motion. In these days of advanced scientific knowledge men often strive to attain ends which are equally ridiculous. A few years ago many of us were invited to see a deep mine pump, which the inventor said would raise immense quantities of water, with only sufficient power or force exerted to overcome friction. We found he had two rising mains or columns of water, with a piston pump at the bottom, and when working he fancied that the weight of one column of water acted upon the piston and lifted the other, forgetting that it had lowered itself a distance equivalent to the height the other had been raised, and that he could simply establish an equilibrium. Labor and expense were lavished upon this pump, of course to no purpose, and a description of it, with an engraving, actually appeared in one of the London scientific papers. The cleverest thing I ever knew attempted was a man trying to lift himself in two milk cans with the yoke over his shoulders. He managed very well till the bottoms came out of the cans, and the cylindrical portions flew up his legs. Unfortunately for themselves a large portion of those engaged in engineering (mining, civil, and mechanical) and other scientific pursuits never begin low enough—i. e., with the study of natural philosophy; or they disregard it as being of no moment, or too elementary, whilst others are only practical men without theory, and, consequently, strangers to the facts. Practice can feel its way a considerable distance without theory, but theory is of very little service without practice, as ten minutes of the latter will sometimes upset ten years of the former. The two together are valuable, and is the happy medium we want. In the instances I have related had those interested known and kept in mind the fact that under no circumstances whatever is it possible to create power or force, they would have saved themselves much trouble.

I would urge, upon young members especially, to closely study natural philosophy, and to keep in mind the following facts: It is impossible to create matter, and it is equally impossible to destroy it. Power or force is exactly subject to the same conditions as matter in these respects, and when effect is to be gained an equivalent power has to be exerted, or, in plain words, the work done by any machine is the same as the work applied. The discovery that power is indestructible is one of recent date. Count Rumford found that in boring cannon by horse power sufficient heat was given off to boil water; heat, in fact, is nothing more than another form for motion, and whenever you exert power heat is generated. Dr. Joule brought this discovery to a practical basis, for he determined the mechanical equivalent of heat, which is that a weight of 772 pounds falling through a space of one foot will generate sufficient heat to raise the temperature of one pound of water 1° Fahr. Gravity acts separately upon every particle of matter, and consequently equally upon all bodies, so that a weight of lead and a feather if dropped from any height would reach the earth together if it were not for the resistance of the atmosphere. I have known the peculiar properties of water or other liquids often puzzle even mining engineers, who could not understand how they communicated pressure. Any bulk of water presses equally downwards, upwards, and sideways, according to the head which is connected with it, and this equivalent to 433 pounds per square inch for every foot in depth. I will not trouble you further, but if my remarks induce young members to study the important laws and conditions of nature I shall be extremely gratified.

OIL FROM WOOD.—In Sweden the manufacture of illuminating oil from wood has become a large and successful industry. The roots and stumps of trees are employed for the purpose. The wood is subjected to dry distillation, with exclusion of air, and a variety of products are formed which are of value in the arts. Among these may be mentioned turpentine, creosote, tar, acetic acid, charcoal, oil of tar and oil of wood. The wood oil cannot be burned in an ordinary lamp, but a camphene lamp can easily be adapted for the purpose. It is not explosive and is remarkably cheap. The pine tree is the best adapted for distillation, and there are 15 establishments in operation in Sweden, three of which produce 15,000 liters (887 gallons) of oil annually.

QUICKSILVER FIRE ALARM.—A fire signal, to indicate the breaking out of a fire, which has lately been patented in France by Angelin, operates as follows:—When the temperature of the apartment rises above a predetermined point, a quicksilver thermometer is caused thereby to break, and the quicksilver runs into a dish, where by its weight it sets in motion a clock work. This last is made to operate an alarm bell.

The Latest Arctic Expedition.

Iron says: It is a pity that the Admiralty have not thought fit to publish fuller details of the expedition. A number of documents, such as the sledging journals, have indeed been printed, and even circulated, but amongst a very limited coterie. It would almost seem as if it were wished to suppress the painful details—tragically painful they are described in a well-informed medical journal, which says that the sufferings of the men engaged on the sledging expeditions were frightful. "Before they were out a week or a fortnight they were ravaged by scurvy; their limbs swelled; their teeth fell loose; the blood was effused in patches; one-half of them became prostrate, fetid, miserable beings, whose existence was intolerable to themselves and those around them. Every sledge party, without exception, broke down prematurely from scurvy. Not only so, but the disease seems to have taken all the commanders of sledge parties by surprise; each in turn expresses his astonishment, horror and terror of this affliction when, its full force being felt, he can no longer shut his eyes to its nature, and each bewails pathetically his want of lime-juice." Nothing like this has befallen any maritime expedition since the days of the ancient navigators, to whom the anti-scorbutic virtues of lime-juice were unknown. It is evidently not to the officers of the expedition that this lamentable breakdown is to be attributed; they appear to have been fully aware of the virtues of the prophylactic so strangely neglected; but it is rumored that the Whitechapel land at Whitehall sent out the ships, otherwise splendidly provided and manned, with a short supply of what is by common consent, and from about a century's experience, considered an almost perfect preventive of one of the gravest dangers of long voyages. Mr. Clements Markham and other defenders of the Admiralty have been insinuating that lime-juice is not so effective as it is generally believed to be, but that fresh meat is the only remedy, forgetting that even the long acclimatized Eskimos are often affected by scurvy, although they live exclusively on meat, and never use salt. In such cases they apply to scurvy grass, the well-known anti-scorbutic.

Mine Signals.

At the late Brussels exhibition two appliances for mine signals were exhibited by Messrs. Siemens and Halske, the eminent electricians of Berlin, whose stand, superintended by Herr Ran, of Brussels, was one of the most crowded during the exhibition. An appliance for giving bell signals between the bottom of a shaft and the several heights of workings, is quite independent of batteries, and consists of a magneto-electric induction machine producing alternate currents, and connected by a special cable with induction bells. The inductor contains six permanent magnets, between which a Siemens armature is made to revolve by means of a handle, thus generating currents which act upon the bells. This system does away with the difficulties and shortcomings of bells worked by batteries, as the magneto apparatus is of constant and unchangeable power, is portable and protected against damp, and is not so liable to be damaged by rough handling as battery arrangements are. To give a signal to the distant bell, it is only required to turn the handle of the inductor at the place from which the signal is sent. When two instruments are connected, signaling can take place from both ends; but, in cases where signaling is required only towards one end, the alarm bells can be separated from the inductor and placed at the receiving point while the inductor stands at the sending end. This appliance, entered in class VI., Germany, was exhibited by the government administrative of the Saarbrück mines, in which none but electro signals are allowed to be used, and also none but machines for signaling which are independent of batteries.

SIPHON.—A new siphon is described by M. Antolke, in Poggendorff's Annalen. The modification consists in furnishing the shorter arm with a valve. This arm terminates at about the middle of a short wider tube, in which it is held by a cork stopper, reaching just as far and having grooves on its lower surface. Further down in the enclosing tube is another stopper, with aperture a little wider than that of the siphon; and in the interval between the stoppers is a glass disc, free to move up and down. In using the apparatus you simply move the shorter arm up and down several times in the liquid, which then rises up to the head and flows over. The phenomenon depends on the inertia and adhesion of the liquid. With this siphon it is not necessary to draw out the air by suction nor to apply the finger to the aperture of overflow.

PIPES AS ELECTRIC DISTRIBUTORS.—Cast iron pipes of several feet in length, and with collars nearly three times the diameter of the pipe cast thereon, like the pipes used for heating purposes, have been used with good results as distributors, deep in the earth, of electricity brought down by lightning conductors. A length of copper pipe about four times the diameter of the lightning conductor being fixed in the top of the iron pipe, stands some distance therefrom, and partly above ground. Below the distributing flanges a pointed and perforated cast iron pipe is attached, the length of the whole of the pipes being about 30 feet, and the conducting rod penetrating nearly to the bottom of the lower pipe.

HERMANN SCHUSSLER, the accomplished hydraulic engineer of the Spring Valley Water Works, has received an invitation from the West Side Irrigation District Company, at Grayson, to take the place of consulting engineer there. He has, however, felt himself compelled to decline this honorable compliment, owing to his professional engagements in this city.

UTAH has more miles of narrow-gauge road in operation than any State or Territory in America.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR.

MINING NOTES.—Amador Ledger, Jan. 6: The Volunteer has recently passed into the hands of wealthy men of San Francisco, who are determined to give it a thorough testing. The Volunteer joins the Kennedy. It has been prospecting to a depth of 130 feet. The rock from the surface down has been of a paying character, ranging from \$8 to \$15 per ton. Since the purchase was completed, preparations have been pushed forward for getting the mine into working shape. A wagon-road has been constructed from the mine to the main road, to facilitate shipment of ore. A substantial building has also been erected over the shaft, to contain the machinery for hoisting purposes. In the rear of the main building is a blacksmith shop. A "donkey" engine was actively at work during the time of our visit hoisting water from the shaft. The shaft will probably be drained by the end of the week, and the miners will commence operations immediately thereafter.

MAHONEY.—Reports from the Mahoney mine, at Sutter Creek, are encouraging. A. D. R. Stewart, with capitalists of San Francisco, have the control of the property and are working it with vim. To show the improving prospects, we may state that a short time back only between 20 and 30 men were employed; now the number reaches between 50 and 60. Until lately the ore extracted was equal to keeping only 10 stamps of the Lincoln mill running, now the full power of the mill—40 stamps—is being crushing the rock.

LINCOLN.—Appearances tend to show that the mine will be started up at an early date.

GOOD HOPE.—C. Peters, the principal stockholder in this mine, is having timbers and lagging hauled on the property, with a view of resuming work as speedily as possible. The mine, on the main quartz belt, just inside the limits of the Lincoln. The prospect is favorable for a good mine. A shaft is down over 100 feet, the ledge at the bottom being six feet wide, apparently getting deeper and wider as depth increases. The last crushing at the Volunteer mill, we are told, paid upward of \$6 per ton, without taking the value of the sulphurets into consideration. The mine is incorporated, with a capital stock of \$500,000, divided into 500 shares of \$10 each. The articles of incorporation provide that no assessment shall be levied for more than five cents per share at one time. Only about 600 shares have been disposed of—not sufficient to justify the levying of an assessment to provide working capital. Peters is desirous of selling at least 10,000 shares, so as to be able to work the mine straight along.

CALAVERAS.

WHAT CHER.—Calaveras Chronicle, Jan. 6: We learn that work has been resumed in the well-known What Cheer claim, Chile gulch, by some parties who have been relocating the ground. There are a number of other abandoned claims in this vicinity that will yet be relocated and successfully worked.

LYNN COURTESY MINING JOURN.—Mr. M. Cary is erecting a 10-stamp mill on the Doyle mine at West Point. The machinery will be ready for operations shortly. F. C. Hall, of Lone City, is preparing to put a mill on the well-known Zacator mine. The machinery will be on the ground in a few days. The new hoisting works at the Sanderlin mine, Mosquito district, are working splendidly. The work of sinking the shaft has been recommenced, the ledge developing very favorably. Rich rock continues to be taken from the old Holmes mine, Grisswald & Co., proprietors, Mosquito district. A small quantity of rock—about 17 tons—from the Greenhorn mine, Mosquito, crushed in Harris's mill, yielded \$80 per ton. Messrs. Potter & Rodgers are the lucky owners.

EL DORADO.

GRIFFITH CONSOLIDATED.—Mountain Democrat, Jan. 6: Last Monday, at the Griffith Consolidated mine, a large slab, weighing several hundred pounds, was taken out from the grand bonanza, which was noticed in a former issue of our paper. This slab is sprinkled and permeated all over with free gold, and about midway of its depth, running through it from end to end and from side to side, is a belt about two inches thick, composed wholly and in about equal parts of black sulphurets and fine free gold.

EXTRAORDINARY ORE.—We have been permitted to inspect a few samples of ore taken from the 830-foot level in the St. Lawrence mine within a few days. It exceeds anything previously seen from the exceedingly rich bonanza in that mine. Explorations upward from the point where this bonanza was first struck, composed wholly and in about equal parts of black sulphurets and fine free gold.

INYO.

INYO CONSOLIDATED.—Coso Mining News, Jan. 6: We understand that Wm. Walsh, an old-time mining man, who has been with us for the past week or two, has succeeded in purchasing the interest held by several parties here in the Inyo Consolidated mines, and has gone below to make arrangements to commence work upon them at an early day.

TEN THOUSAND.—The Modoc mining company celebrated Christmas by making her ten thousand bar of bullion. Both furnaces are running well, water plentiful. The value of the bullion shipped for December amounted to \$88,090.

LIDA VALLEY.—Inyo Independent, Jan. 6: Things are now distressingly quiescent out at Lida. The mill stands in idleness, with little prospect of resuming business within any definite period. But there are men we know of who maintain that the camp will yet at no distant day flourish with the best of them.

TO-DAY.—The entire property of the Silver Sprout mining company, including the mines, mill, ranch, water-right, etc., will be sold by the sheriff to-day, in the suit of Harris & Rhine. The company will doubtless redeem long before the six months' term has expired.

MARIPOSA.

MARIPOSA TUNNEL.—Mariposa Gazette, Jan. 6: In one of our late issues we mentioned that the vein had been struck by the main heading. The good news then published to the people was a mere idea of what was in store, when this bonanza was first struck, composed wholly and in about equal parts of black sulphurets and fine free gold.

NEVADA.

KENTUCKY RIDGE MINE.—Grass Valley Union, Jan. 6: Work at this mine is progressing well, and all the indications there show that the undertaking will pay. Sixteen tons of ore have been taken out of the incline on the larger ledge, and from that ore specimens have been culled and worked in a hand mortar, and the red dirt clinging to the ore has been washed through a rocker. From this mortar and rocker working gold to the value of \$421.10 was realized. Then four loads were taken from the ore that had been culled, and worked by mill process, yielding \$19 to the load. The shaft has more than doubly

paid for itself in its sinking. The bottom of the shaft is in light galling ground and has a strong ledge of 18 inches in thickness. The upper tunnel is into the ledge, and drifts from it. On the ledge, have been run 120 or 70 feet in drift ore. This tunnel gives over 500 feet of backs. The Kentucky Ridge will soon have a mill of its own.

MALTMAN'S CHLORINATION WORKS.—Nevada Transcript, Jan. 7: We found Oscar Maltman busily engaged with a crew of workmen yesterday, putting up extensive additions to his already extensive chlorination works. When the present improvements are completed the establishment will be the largest and most complete in its department in any in the State. Mr. Maltman was one of the first who practically worked sulphurets by the chlorination process, and is, we believe, now considered the most successful manipulator of sulphurets. He started in with a 12-foot furnace in 1860, and has made gradual additions until it is now 70 feet. The main building now used is 44x30 feet. The chlorination room is 30x20 feet. There is an assay room and several other rooms connected with the establishment. Five thousand pounds of sulphurets is considered a fair day's work, but if necessary the amount can be increased. The ore is mostly obtained from the mines in this district. There is also a miniature quartz mill connected with the works, with which small lots of ore can be tested by mill process. It is run by steam, and is the only one of the kind in the country. To those engaged in prospecting it is very convenient, as it can readily be determined by it what rock will pay by mill process before great expense has been incurred. As soon as the improvements now being made are completed, his works will be capable of reducing all the ore brought to it, with dispatch, and of giving the most satisfactory results.

WATER.—San Juan Times, Jan. 6: Water for mining purposes is becoming very scarce, and unless we have a plentiful supply of rain very soon, many of the mines on this ridge will have to close down before the end of this month. We learn that the Milton company contemplate closing down on some of their mining operations, within the next ten days, for want of water. The summer weather we have been experiencing for the last six or eight weeks is hard upon the miners, since the above was put in type we learn that the Manzanita mine at Sweetland and the Milton company's mine at the Corral shut down on Thursday last.

PLACER.

ALTA.—Placer Herald, Jan. 6: The mining interests of Alta have received a new impetus through the energy displayed by Andrew Larson, who has been prospecting for the blue gravel lead a long time. Mr. Larson ventures an opinion that the lead is a continuation of the noted Hidden Treasure at Danacuss, as its course is in the same direction.

IRON SMELTING.—Fitzhugh, the gentleman who made a strenuous effort about a year ago to open the iron deposits near the line of the railroad, above Clipper Gap, and erect smelting furnaces thereon, was again in Auburn during the early part of the present week, on business, we understand, connected with the same project. What encouragement he is meeting with we did not learn, particularly, though a gentleman whom we noticed in conversation with Mr. Fitzhugh, more or less, said to us: "The thing will very likely be go this time."

THE MINES.—Placer Argus, Dec. 30: The St. Patrick is doing well. Sinking the main shaft has been suspended for the present, and the 620-foot level is now being run. This level is yielding good ore in sufficient quantity to keep the mill steadily running. The mill is answering the expectations of its owners fully. The satisfaction of the prospectors for the great bonanza, with 100 inches of water they have all the power needed. As run now, the profit and operations will be much larger than formerly, the saving of expenses alone being enough to pay a fair dividend on the cost of the mill. The Good Friday is taking out some good ore and have a large lot on their dumps. Shurtliff has sunk a new shaft east of the one at the top of the hill, and has now reached a level now drifting west to connect. The Julian is running out a large quantity of low grade ore, and the working pays very well. There is more than the usual amount of prospecting going on, the fine weather permitting work in the mines to proceed without interruption. Rich developments are expected. The Eclipse mill is running steadily and doing good work. Just below it Cooper is prospecting for the gold, which he has been in operation. This is a mill of a new pattern, in which heavy pestles, with a sliding and rocking motion, are used to crush the quartz. It was begun about a year ago, but work was suspended until lately.

IRENS.—Dutch Flat Forum, Jan. 6: There is but little change to note in mining matters since our last. The various claims in this and Gold Run districts are all quiet, and are quietly waiting for water. The ditches of the South Yuba canal company and Miners' ditch company are dry. The ditch of the Cedar Creek company still has a small head running, sufficient to wash in the Baker claim part of the time. The Baker is the only claim in this section that is washing. The work of opening is progressing remarkably well. The pit is rapidly reaching, and the shaft below which the ore is in drifted ground to interfere, and is now in condition for a successful winter's working, provided we have rain.

SANTA CRUZ.

PLACERS.—Santa Cruz Courier, Jan. 5: The gold discovery reported on the lands of Hames and others, has been confirmed. In the section alluded to there is a stratum of auriferous gravel, in which gold can be found anywhere. Last May a woodchopper in the employ of J. J. Boyle, observing the formation and appearance of the country, prospected for gold in a gulch, and found color upon every trial. The depth of the gravel deposit is not known, as it has never been sunk upon; but we would not be surprised to hear of rich deposits of gold being found in this section.

SIERRA.

FOREST CITY.—Cor. Mountain Messenger, Jan. 6: The Bald Mountain Co. have laid off most of their crew until water comes, and the famous pioneer engine is quickly waiting for some mud below, but trying it, it must be that it is too low down to demonstrate that it was a success, and solve the Chinese problem, for Forest City at least. The North Fork Co. are steadily forcing their way, at a heavy expense, toward their pay. They have dump, shop, flumes, reservoir, etc., all completed, so that they lack nothing but the tunnel and water to wash, before the shareholders get back some of the Irish dividends they are paying in now. The South Fork Co. have not been doing much since they sunk their last shaft. This company have sunk two shafts in their tunnel, and shown the presence of a rich and well defined channel running through the claim, and nothing is wanted but a drain tunnel to make it a paying mine. There is a good chance to drain by starting below the old Live Yankee, and nothing is wanted but a drain tunnel to make it a paying mine.

LEDOZ.—The workmen in the Brush Creek mine, at the Mountain house, have struck a ledge of nice looking rock in the mine.

GETTING READY.—The China company are getting ready to work off their Williams place, having just got their drift ground in order.

TUNNEL.—Wm. Meserve is running a tunnel under the court house lot. Good pay was got there in days gone by.

SONOMA.

NEW FURNACE.—Sonoma Democrat, Dec. 30: We are informed that the new furnace at the Cloverdale mine for working fine dust and gravel is a perfect success under the superintendence of B. C. Hughes. It was started on Saturday, the 10th inst., and up to Thursday cleaned 100 tons of fine dust. This mine has been producing metal for two years from February 12th next, steadily from thirty-three to thirty-five flasks a month, with the old Knox & Osborn condenser. The new 10-ton furnace will largely increase the yield. There is metal enough out to run the furnace for eighteen months, and enough in sight to run it for two years. The Cloverdale is undoubtedly a great mine. We are indebted to William Ray, of the

mine, for these interesting particulars.

TRINITY.

ALTONA QUICKSILVER MINES.—Dutch Flat Forum, Jan. 3: Mr. C. A. Lawrence, a former resident of Dutch Flat depot and Gold Run reports the following from the Altona quicksilver mine, now worked under his supervision: It is located twenty-four miles northeast of Trinity Centre, Trinity county, about twenty miles of ground in the vicinity of the ledge, having an average depth of ten feet of soil, is being removed by hydraulizing, and the decomposed cinabar found therein yields six flasks per day. The ledge, along the surface of the bedrock, has a width of four feet, but a shaft which is now sunk sixty feet, shows it to be thirty feet in width, and with this increase retains its richness, which is 10 per cent. quicksilver. A tunnel 700 feet in length is being run, and when completed will take the ledge at a depth of 140 feet. If the present prospects in the opening of this mine continue as they promise to do, it will in a few years eclipse any cinabar mine on this coast. This valuable property is owned by Mark Zellerbach, of San Francisco, with the exception of what Mr. Lawrence owns, which is enough to be considered quite valuable.

TUOLUMNE.

NEW ALBANY.—Tuolumne Independent, Jan. 4: The miners at the New Albany are down on the vein (passing through the fissure on the way), 520 feet in a perpendicular shaft. This is the deepest cinabar shaft, or the most expeditious from the time the company commenced, of any that has been sunk in the county. The result of this experiment, we are confident, would prove that depth in such ledges as the New Albany is all that is required to make mining property lasting and paying institutions beyond a doubt. However, the depth they have already obtained in pay rock will have a marked effect in this direction.

PHILADELPHIA DIGGINGS.—These gravel diggings, in the mountains above Columbia, are being rapidly put in readiness for active work. The 15-inch pipe, 1,430 feet long, put together on the ground, is completed and is being put in place. The company are now at work with fifty men, placing flume and building ditches—having about seven miles of ditches surveyed. This claim has an extent of four miles, six hundred feet in width, with all the defined lines of an ancient gravel deposit.

Nevada.

WASHOE DISTRICT.

BEZCHER.—Gold Hill News, Jan. 10: Opening the 1800-foot shaft will be commenced in three to four days. Sinking the main incline is making fair progress, notwithstanding a strong flow of water. The daily yield of ore is about 10 tons, the assay value is \$23 to \$30 per ton. The Eureka mill has been stopped, and the ore is now being crushed at the Santiago.

JULIA.—The face of the west cross-cut from the main south drift on the 1800-foot level is still advancing in quartz, giving low assays but steadily improving in value. A south drift has been started on this body of quartz, the full size of which is in depth of shaft, 316 feet below the 400-foot station, with the bottom in very favorable quartz, with streaks of porphyry and clay. A shift of men are put to work clearing out the main west drift at the 400-foot level in order to ascertain if the west wall of the ledge has been reached at that point.

UNION COX.—The prospecting on the 1300-foot level is being pushed ahead as fast as possible, and so far with very encouraging results. The main north drift on that level, driving forward through the center of a fine vein of quartz, is showing steady improvement. The winze, sinking on the same vein farther to the southward, is making good progress and gives good assays in both gold and silver, improving in value.

YELLOW JACKET.—The face of the cross-cut at the north ledge, on the 1340-foot level, is in quartz, carrying some pay ore. At the 2040-foot level the cross-cut west is in 250 feet north from the south winze, face in quartz and porphyry with seams of good ore.

MEXICAN.—The mine looks very favorable in all the prospecting sections. The main north drift on the 1700-foot level is steadily advancing along the west wall of the ledge, the face in spar and millstone, which, during the week, has shown a slight though steady improvement in the value of the ore assays.

LADY WASHINGTON.—The drift north from the main east cross-cut at the 850-foot level is now in 82 feet, still following the excellent and very promising ore vein heretofore mentioned, and which still holds out well in both width and appearance.

CALIFORNIA.—Daily yield, 500 tons of ore. The ore stops on the 400, 1500 and 1600-ft. levels continue to yield the usual fine character of ore, and show no signs of depletion. The yield of bullion for the month of December was \$1,278,648.21. The usual dividend of \$2 per share, aggregating \$1,080,000, was declared yesterday, leaving a balance of \$198,648.21 with which to pay the running expenses for the month. The main south drift on the 1000-foot level has shown a steady advance in the ore, and is rich. The south drift on the 1650-foot level from the deep winze is steadily advancing to connect with the drift from the C. & C. shaft, the face still in very rich ore. The west drift from the C. & C. shaft is making the best of progress. The new ore dump at the C. & C. shaft is completed and connected with the shaft by a trestle work, ready for the shipment and millinery of ore. The completion of this drift and the battery mill at that shaft will shortly enable the shipping and crushing of a largely increased quantity of ore, and thus necessarily greatly increase the bullion production of the mine.

CHOLLAR-POROS.—The main incline shaft is now down thirty feet below the 1700-foot level. At the 1700-foot level a station has been put in. Sinking the Combination shaft is making best time for progress. There is no occasion whatever yet for running the pumps. This shaft is now down a little over 1,000 feet. Daily yield, 100 tons of ore, the assay value of which is \$20.50 per ton.

JUSTICE.—Daily yield, 340 tons of ore. The ore stops extending from the 400 down to the 800-foot levels are all yielding the usual amount of good milling ore, and at no time in the usual downward progress of the mine is there a poorer lot than now. Good ore is found on every level yet opened, and the bottom of the winze extending downward from the 800-foot level is showing as fine ore as that has yet been discovered in the mine. The yield of bullion for the month of December was about \$280,000, leaving a handsome profit over all expenses.

SIERRA NEVADA.—The north drifts on both the 1500 and 1250-foot levels are each making good progress, and are both showing a much more favorable mixture of quartz in the face as they advance. The prospects of a concentration of the ledge and ore to the northward on the 1000, 1250, 1550-foot level is growing better every day. The large new air-blower recently erected greatly facilitates work.

SAVAGE.—The pumping, since the insertion of the new piston, is making a fine time for progress. The water did before. It now lifts water from the 1800-foot level with just as great ease as it did from the 1700-foot level before the insertion of the new piston. During the stoppage of the engine to put in the piston the water rose a considerable distance in the shaft, but was lowered again with the most perfect ease as soon as the engine was started up. The 1800-foot level is now very clearly of water, but the heat at that point is intense.

BALTIMORE AND AMERICAN FLAT.—The face of the northeast drift on the 1400-foot level is showing a steady improvement, more quartz appearing every day. The face of the upraise from the 1050-foot level is showing some very rich ore some of the ore assays up into the thousands. The main winze being sunk below the 1650-foot level is still showing a strong bonanza below the 1650-foot level.

ORISKANY.—The yield of ore at present is very light, and the quality not so good as heretofore. The prospecting work in every quarter of the mine is being pushed ahead as fast as possible. The main incline is being pressed downward, to reach the 1800-foot level at the earliest moment possible.

ARGENTINA.—The drift from the ravine is completed to its connection with the shaft, and sinking is resumed. This drift is a very judicious arrangement,

adding much to the facilities for opening and working the mine. It not only gives splendid ventilation, but will save nearly 100 feet of hoisting or pumping.

LIBERTY CONSOLIDATED.—During the first part of the week a disarrangement of the pumps at the 2000-foot station occurred, causing a slight delay in the work on the lower levels. Everything has been repaired, however, and is again in the best of running order.

NORTH CONSOLIDATED VIRGINIA.—A strong flow of water was encountered on the 1100-foot level during the fore part of the week, which created a delay in the pump work, however, kept busy, and last night the water was again drained to the bottom of the shaft and work resumed.

NIAGARA.—Driving the prospecting drift on the 680-foot level is making excellent progress. During the week a fine vein of ore, ranging from three to eight feet in width, has been opened upon by this cross-cut. The ore in this vein is rich and will to all appearances mill from \$50 to \$80 per ton.

COX VIRGINIA.—Daily yield, 275 tons of ore. The ore stops are looking well. The enlargement of the drifts connecting with the Gould & Curry, on the 1500-foot level, is making good progress, and is greatly benefiting the air circulation on the lower levels. The dividend for the month of December was passed, there not having been a sufficient amount of bullion to produce a dividend. The main west drift from the C. & C. shaft must soon cut the ore vein at that point, when there is but little doubt that the regular amount of bullion product on dividends will be resumed.

GOULD & CURRY.—The pumping compartment of the shaft has been repaired throughout and the entire shaft is now in better condition for use than it has been for years past. The erection of the new pumping machinery is making the best of progress.

OVERMAN.—The new pumping engine and pumps are now ready for active use down to the 1400-foot level. The prospecting drift at the 1300-foot station is gradually draining the flow of water at that point and lessening the pressure of the head.

WALKER & HAZEN.—The enlargement of the drifts on the 1500 and 700-foot levels has greatly improved the circulation of air, and will soon enable the development of both of those levels in a much more perfect manner than ever before.

CALADONIA.—The north drift on the 1150-foot level, running to connect with the south drift of the Overman, is advancing in very favorable ground, and has about 150 feet yet to run to complete the connection.

SOUTH COMSTOCK.—The fine quartz vein developed by the main drift east at the 300-foot level shows a width of 14 feet, with no east wall yet. Some streaks in it assay as high as \$40 to the ton.

NEW YORK.—The third or pump compartment of the shaft is being pushed forward to completion as fast as possible, although considerable work remains yet to be done.

SILVER CITY.—The lower level from the bottom of the incline is opening out finely, with plenty of good ore in sight and being developed. Under the former management these lower workings were being opened in a workmanlike manner, and were left in good shape when the great influx of water and insufficient pumping machinery compelled the abandonment.

FLORIDA.—The north drifts on both the 700 and 500-foot levels continue to show better every day. The chances for the development of a paying body of ore in that portion of the mine at no distant day are very encouraging.

SILVER HILL.—The east cross-drift on the 650-foot level is steadily advancing, the face in very favorable vein matter.

BRYAN.—The erection of the new pumping machinery is making the best of progress.

SUCCESS.—The water has been drained from the shaft. The new pumps work admirably.

TRIOAN.—The ore developments in both the north and south drifts on the 300-foot level were never more promising than at this time.

KOSMUTH.—Work is progressing splendidly on both the 500 and 700-foot levels, with steadily increasing prospects of the development of a splendid body of paying ore on the 600-foot level.

COSMOPOLITAN.—The ore-producing sections continue showing well and yielding their usual amount of ore.

AMAZON & GLASSBORO.—Work in this noted mine was resumed yesterday under the most favorable auspices, and will be pushed forward hereafter with renewed energy.

BRYAN.—The Hope mine has been started up on ore from this mine. The ore yield from the 350-foot level is gradually increasing.

BALTIMORE.—Face of north drift in favorable working vein matter, with streaks and bunches of low grade ore.

SUPERIOR.—The tunnel from the ravine is now within 40 feet of its point of connection with the shaft.

HALE & NORROSS.—The pumps are gradually and successfully reducing the flow of water at the bottom of the shaft. The drift connecting the Hale & Norross and the Savage on the 1000-foot level is being cleaned out and repaired as rapidly as possible, in order to get a circulation of air between the two mines, and thus allow the heat.

ANDES.—The appearances are that a paying body of ore is about to be opened up in the east cross-cut on the third station level.

EUREKA DISTRICT.

STRIKE.—Eureka Sentinel, Jan. 2: An immense strike has recently been made in the Hamburg mine. The ore body, which is principally molybdate of lead and rich in silver, was found in the 80-foot level of the Pacific shaft. The bonanza has been drifted into 12 feet without any sign of a wall, and from other explorations in contiguous portions of the mine, it is probable that 20 or 30 feet further will be run before striking the limit. Other bodies of ore of considerable magnitude have, during the last few months, been discovered in the Hamburg, but nothing approximating in extent to the latest strike, which will doubtless prove the most extensive ever made in the district, outside of Ruby Hill.

CONDITION OF MINES.—Eureka Sentinel, Jan. 7: Since our last general review there have been some developments of importance that have given a cheerful stimulus to the business outlook. The railroad facilities, open winter and good roads have enabled the mines to receive supplies without interruption, and, as a consequence, instead of the usual cessation of work, there are rumors of furnaces starting up, important ore bodies found, the development of which will insure an increased demand for labor and supplies. The most important mining news of the week is the strikes in the Consolidated and Jackson, and the firing up the furnace at the former.

ETREKA COX.—We incorporate the official letter of the superintendent, Jan. 6th: A body of ore has been discovered on the 6th level, and so far as developed prospects favorably, showing a good quality of ore.

CLARK & BENTLEY.—The pumps are gradually sinking and sinking to ascertain the extent of the furnace run, with almost certain guarantee of continuance during the season.

RICHMOND.—Hoisting 200 tons per day. Branch railroad completed to furnace and ready for operation.

ATLAS.—Main shaft nearly completed. Drift from old works in 500 feet. Ten men prospecting and cross-cutting. Plenty of smelting ore in sight.

CLARK & BENTLEY.—Important developments during the week. Drift penetrated ore body 10 feet. Ore assaying \$35 gold and silver. It is impossible to give the extent or value of the discovery, as all connected with the mine are very reticent.

K. K.—Fine body of ore in the mine and plenty on the dump; furnace running well. The deposit in this mine is increasing daily in proportions. There is an immense amount of ore in sight, one of the largest bodies in the district.

HOUSAC.—Four men employed retimbering and cleaning out the old stopes and putting the mine in order.

ORANGE.—Extracting ore of high grade and shipping to Silver West furnace.

CLARK & BENTLEY.—Taking out 25 tons daily, assaying \$30 per ton. Mill crushing 10 tons per day and will increase the quantity very soon. The new ore development increases in quality and extent. First shipment of

Moonlight on the Susquehanna.

What a legacy of beautiful names the Indians have left us! Strike from our geographical nomenclature all of Indian origin, and you eliminate from it almost all it has of grace and beauty. Compare the Wachusett, Juniata, Suwanee, Mississippi, Shasta, Tacoma, of the Red Men, with the "Bald" mountains, "Black" rivers and "Goose" creeks of the white settlers. And think of "Susquehanna!" Does not the very name breathe beauty and poetry, almost tempting us, without further knowledge, to believe with Buchanan Read,

"None half so fair as that broad stream whose breast
Is gemmed with many isles, and whose proud name
Shall yet become among the names of rivers
A synonym of beauty—Susquehanna."

"It is difficult to imagine," says another, "a more continuous line of beauty than the course of the Susquehanna, a river whose mild grace and gentleness, combined with power, render it a message of nature to the affections and to the tranquil consciousness. This trait of mildness, even in its proudest flow, seems to hover upon its banks and waters as the genius of the scene. No thunder of cataracts anywhere announces its fame. It is mostly the contemplative river, dear to fancy, dear to the soul's calm feeling of unruffled peace."

This is the poetic aspect, and from this aspect should the "moonlight scene" upon this page be viewed to be fully appreciated. But the Susquehanna has other associations than those of beauty. It has been made an historic stream by deeds of blood and massacre exceeding all others in the darkest pages of colonial history. Wyoming and Cherry Valley are upon its banks. It marked, too, the limit of rebel invasion into the North. Never did a Grey coat succeed in crossing its waters, though they several times reached its western bank.

A peculiarity of Pennsylvania geography is that the rivers have not the same direction as the mountains, but generally run at angles to them. Instead of gliding quietly between or along them, they seem to decide which is their shortest route to the sea, and then push boldly forward for it, let what obstacle come that may. Of this eccentricity, as it may almost be called, the Susquehanna is chief representative. Numberless seem the mountain ridges and hills through which it has cleft in its

course to the Chesapeake. In some places it passes through as many as five of the so-called "gaps" or "narrows" in the distance of 20 miles. Almost its entire course is through the mountains, and it has all the characteristics of a genuine mountain stream, being usually broad, shallow, and rapid, with here and there long stretches of calm, deep water. Its bed is very rocky and in many places is studded with beautiful little islets. In the lower portion of the river's course its general width is about a mile, narrowing occasionally to half a mile or even less.

For purposes of commerce the river has little value, owing to its shallowness. In the summer it can be forded almost anywhere. But in the winter and springtime, when its banks are full, it opens a road to market for the vast quantities of lumber in the densely wooded regions about its headwaters, and many are the thrilling adventures of the strong-armed, steady-nerved men who pilot the great rafts down its turbulent current and successfully "shoot" all its rapids and "dodge" all its islets and sunken rocks on their way to the lower country.

DRYING APPARATUS.—In the apartment of the new and magnificent structure erected in Oxford, England, allotted to the experiments in electricity of high tension, an apparatus of remarkable ingenuity has been provided for keeping the air of the room dry. This apparatus consists of a heated copper roller, over which passes an endless band of flannel; the roller is heated by means of gas lights within it, which, being constantly burning, cause every part of the flannel to become hot. The vapor which arises from the heated flannel is carried off by the current of air which supplies the burners inside the roller. The flannel, when thus dried and cooled, passes into the open air of the room, when it again absorbs moisture, and thus the air of the room becomes so dry that the electrical instruments are preserved in a highly insulated condition, thus admirably meeting all the requirements of the case.—*Ex.*

The American Mine.

On Tuesday last we made a visit to the American mine and made a brief examination of the works. At the time of our visit the pipes were in full blast, throwing a body of water on a bank of blue cement, large enough to turn an overshot wheel to a grist mill. The cement is very hard, requiring to be broken by the use of sledge hammers. Several men were employed at that work, while others again were employed in breaking rock in bedrock cuts, preparing them to be washed away through the sluices. The American company are utilizing 1,000 inches of water daily, using two monitors in piping. The ground they are now washing lies directly in the channel and pays immense. The company have over forty men employed on their works and there is not a Chinaman among them. The company recently constructed a splendid blacksmith shop, which contains two forges. John Bach is the boss of that establishment and works one of the forges and Samuel Lisson works the other. In the shop is a room supplied with telegraph apparatus, the wires from which extend into the tunnel 180 feet beneath the surface, where another similar apparatus is placed with Frank N. Morris as operator; Samuel Lisson being operator in the shop. This telegraph is very useful in the way of giving notice above or below when any article for use is desired. The shaft through which the gold-bearing earth passes is situated only a few

The Isthmus Canal.

Those California farmers who are looking to the cutting of the isthmus for quick shipment of produce to the European markets, may find encouragement for the realization of the project in this week's news. During the week a dispatch was received from Washington stating that the commission appointed by President Grant to examine the three proposed routes for connecting the Atlantic and Pacific by means of a canal, have reported in favor of the Nicaragua route. The *Call*, in commenting on this announcement, makes the following statement: "The commission consists of Gen. A. A. Humphreys, C. B. Peterson, of the Coast Survey, and Daniel Ammen, of the Navy Department; all gentlemen well qualified for the task assigned them. The report they have made was anticipated by the general opinion of professional engineers and non-professional experts who have examined the different routes. We have not the reports of the former commissions before us at this moment so as to give actual estimates in detail, but these reports left little doubt that the Nicaragua route would be finally selected as the most feasible. Still, the work is one of gigantic proportions, and will rank, with the construction of the Suez canal and the building of the Pacific railroad, among the great engineer-

mation concerning the most feasible route was then gathered, has been at the service of the present commission. Thus, if they have changed the route materially they have done so in consequence of the discovery of a better one. The objections which the British government interposed at that time are now overcome by making the work international in its character, by the equal participation of the great commercial powers in its construction and subsequent management. The United States Government is now in communication with the several European nations in regard to the enterprise, and it is expected that the President will soon be in possession of documents which will justify him in submitting the question to the consideration of Congress.

CONTRACTION OF THE HOOF.—A very interesting veterinary operation was performed by Dr. Dunbar, at the stables, 842 and 844 Howard street, in this city, on Tuesday afternoon. A valuable stallion, owned by Judge Green, was severely afflicted by contraction of the hoof. As is usual in such cases, the contraction of the horny hoof had forced the frog up from its normal position, and the pressure upon the joint above had given rise to much inflammation and a bad sore was formed. Dr. Dunbar's operation consisted in cutting away a portion of the hoof and in fitting thereto one of his shoes, contrived

for the special purpose of expanding the foot. This shoe has the sink for the nail holes within the circle of the shoe, which bears the weight, instead of outside it, as in the common shoe. The nail holes slant toward the exterior and thus the "draw" of the nails is outward. The improved shoe has nail holes in the toe and at the inner and outer toe. It has also nail holes at the "heels," but the "quarters" (between the toes and heels) are left without nailing. In the present case the Doctor set the nails in toe and heels of the shoe, and then applying a screw between the heels, he expanded the shoe, and with it the hoof, nearly three-quarters of an inch. This expansion was done in the cold iron, after the shoe was nailed to the foot. The operation will relieve the pressure upon the joint of the foot, and will allow the frog to settle down to its proper place. Now the feet of the stallion will be submitted to a poulticing with flaxseed meal, and it is expected that all inflammation and soreness will disappear and the horse be sound of foot again. Judge Green's horse is a valuable one, lately imported from Maine, and he promises to inform us of the further results of the operation.

SONOMA COAL.—Numerous coal miners of long experience and several gentlemen of considerable scientific knowledge, who have made examination, have expressed the opinion that vast bodies of coal are buried beneath the surface of Sonoma mountain. Prospecting on a limited scale has been prosecuted at times for several years, but only a small amount has been expended in any one place. The indications in most cases have been good, and in several places coal nearly or quite as good as any that has been discovered in the State, has been found in small quantities. One of the most promising of the several mines is on the ranch of A. W. Overhiser, which is situated near the summit of the mountain and about nine miles north of this city. Mr. Overhiser has run a tunnel in the side of the mountain 100 feet, at the end of which he has sunk a shaft 12 feet. The indications are everywhere good, and in several places small pieces of coal that burn readily, and are said by experts to be of excellent quality, have been taken out. The large inflow of water into the shaft caused a suspension of operations, and it was found impossible to go further without the use of an engine. Mr. Overhiser has full faith in the value of his mine, and to the extent of his means will prosecute the work. He invites the attention of miners and capitalists to his property, and a thorough inspection of it.—*Petaluma Argue.*

A NEW SOLVENT FOR COPAL.—Oleic acid is said to be an excellent solvent for gum copal. On heating a small quantity of oleic acid it will dissolve a considerable quantity of copal. It is always a good means of distinguishing genuine amber from the imitation amber which contains copal.—*Druggist's Circular.*

MOONLIGHT ON THE SUSQUEHANNA.

yards from the rear end of the blacksmith shop and so arranged with pulleys and ropes that tools for the workmen in the tunnel can be raised and lowered in a few moments. The shaft is 180 feet deep. It has two compartments, one for passing into it the gold bearing gravel and the other, parties to descend and ascend from the tunnel. The descent and ascent is made by means of a long ladder, which reaches from top to bottom and which stands perpendicular. In this compartment is placed another kind of telegraph with rope and tackle, which notifies the party at the top of the shaft the condition of the sluices in the tunnel, whether running full or otherwise. This is an ingenious contrivance and very useful. The American mine is in tip-top condition and gives promise of paying its owners well for their expenditures. George C. Spooner is the superintendent of the mine and he makes a first-rate one, too. The American company, though not a corporation, is managed precisely as if it was. It has its President, Secretary, Board of Trustees, Superintendent and Foreman. Nearly all the owners are employed in the mine, consequently nearly every gang of workmen has one of the owners with them. We doubt much whether there is a hydraulic mine in this State better arranged and managed than the American mine on Manzanita hill.—*San Juan Times.*

COST OF ENGINES FOR ARMOR-CLAD SHIPS OF WAR.—The contract price to be paid by the Admiralty to Messrs. Penn & Sons, of Greenwich, for the engines, shafting and propellers, boilers, etc., of the twin screw armor-clad *Northampton* is, we understand, £95,500. For the supply of the engines and machinery of Her Majesty's ship *Agamemnon*, the contract for which has just been obtained by the same firm, the cost is to be £90,000. Messrs. John Elder & Co.'s contract price for the engines, boilers, and other machinery of the *Invincible* was fully £120,000, which is, we believe, the largest sum ever paid for the engines of a single ship.

ing triumphs of the age. The Isthmus of Suez connects Asia with Africa, and separates the waters of the Mediterranean from those of the Red sea. Commerce required that this barrier of earth should be removed that ships might pass from sea to sea, and the work has been done. Commerce now requires water communication between the Atlantic and Pacific oceans, and it is only a question of time as to when this work shall be done. The State of Nicaragua does not offer so narrow an obstacle between the two oceans as other points on the southern coast. The width of the State varies between 120 and 240 miles. Lying in the interior of the State, a few miles from the Pacific ocean, is the Lake of Nicaragua, a sheet of water from 30 to 40 miles broad, and only 128 feet above the waters of the Pacific. This lake will be utilized in the construction of a canal. Its depth varies from 30 to 90 feet. The great obstacle to be overcome in constructing the canal is a volcanic range running near the western coast, and rising between the Pacific and the inland lake to a height of 10,000 feet. This State is supposed to show a separation of the great chain of the Cordilleras into two divergent ranges, having a less average height than the main ridge, and being subject to partial interruption. The commission doubtless find favorable passes in these broken ranges which render feasible the project they have in view. The report estimates the cost of the work at \$100,000,000, which our dispatches state to be less than former estimates. There seems to be an error in this. In the year 1849 a contract was entered into between the Republic of Nicaragua and the Atlantic and Pacific Ship Canal Company of New York, by which the latter party undertook to construct the canal for \$20,000,000. The contract was never carried out, owing to the interference of the British government; but the terms were then considered fair by competent judges. We do not know if the present commission follow the exact route the New York Canal Company had selected, but presume that whatever infor-

San Benito County Mines.

Antimony and Quicksilver.

We made this week, says the Hollister *Enterprise*, a general exploration of the mines in the Coast range within the boundary lines of San Benito county. These mines are situated at distances of from 10 to 16 miles from Hollister, on and near the summit of the mountains dividing San Benito and Fresno counties, at an altitude of 3,350 feet above the valley level. The first and most important are

The Stayton Mines.

Antimony was discovered upon the ground by the Stayton Bros., 19 years ago; but as this metal had but little, if any, commercial value at that time, they did not then make any effort to develop their discovery. Thinking, however, from its appearance that the ore might contain a good percentage of galena, some years later they did a little work on one of the claims, in which they unearthed a deposit of cinnabar. Further prospecting soon disclosed the fact that this latter metal also abounded in paying quantities all over the hills. The Staytons went energetically at work to develop their claims. Although for years working under numerous disadvantages, which would have disheartened men of less pluck and energy, they in time made manifest the value of their property. Two years ago the claims, 17 in number, embracing about 460 acres, were covered by a United States patent; the owners being the Stayton Bros., Frank Smith, of Gilroy, and others. After this a small furnace was erected for the reduction of cinnabar, but owing to limited means but little progress was made, further than larger developments of quicksilver ore, which soon commenced to attract to some extent the outside world. The property was negotiated through agents in the London market, and it was believed to be and reported sold three or four times, but the transactions failed and it was not until the present summer that any portion of it changed hands. In July, a company composed of John H. Moore and S. A. Bishop, of San Jose, W. M. Lent, John F. Boyd and Mr. Harper, of San Francisco, men of large wealth and extensive mining experience, bought an interest and immediately set to work putting the property in shape. A large force of hands were employed, the mines opened, two splendid furnaces, ore houses, etc., built, and everything now looks promising for the future prosperity of the works. The demand for antimony being more active, the furnaces are being run on this ore exclusively, and there is enough of it in sight of a high grade to keep five more furnaces continually glowing for months to come. The deposits, of which 50 at least are uncovered, show large bodies of fine metal, and contrary to the accepted theory regarding this class of mines, instead of being found in chambers and deposits, it seems to be in continuous veins which grow wider and better as they go down. Considering the immense quantities of ore, both cinnabar and antimony, the ease and comparatively light expense with which it can be transported to the railroad, the abundant wood and water facilities with which they are surrounded, there can be no question that this is one of the most extensive and valuable mineral locations on the Pacific coast. The description of these mines will apply in a great measure to the other locations on the range, when they are developed to an equal extent, of which the next in prominence is the

Consolidated Wonder Group.

Adjoining the Stayton claims on the north, comprising some 20 promising discoveries. These mines have been incorporated and the stock mostly owned by residents of Hollister and San Francisco. Considerable work has been done in the way of tunnels and shafts, all which disclose good prospects of high and low grade ore. A kiln of brick has been made and burned on the ground, and we understand it is the intention of the owners to erect a competent furnace soon as the necessary arrangements can be made. This is no doubt a very valuable property, and as none of the stock is on the market for the purpose of raising funds with which to build furnaces, etc., a better chance does not offer for profitable investment. A large portion of the pool put up has already been sold, and next spring will see these mines turning out plenty of ore. Still further north and adjoining the Consolidated Wonder is what is known as the

Salinas Mine.

It is also an incorporated company, nearly all the stock being owned in Salinas City. This claim has been worked continuously for several years, and the showing in the tunnels looks splendidly. It has produced a great deal of good ore and has yielded more profit to its owners than any mine in the range. Contiguous to the Salinas mine is the Comstock lode, owned, we believe, principally by Watsonville men. The prospects of the Comstock are now flattering indeed. A large vein of fair ore computed to be 30 feet in width has been cut in the main tunnel, and the proprietors believe they have nothing short of a veritable bonanza. Beside the mines mentioned, there are the Quisen Sabe, Consolidated Ralston and several locations which, as far as developed, promise equally as well as the older claims. There is a world of ore in these hills, and the day is not far distant, if the judgment of experts is not greatly at fault, when San Benito will take rank with the most profitable mineral producing counties of the State.

USEFUL INFORMATION.

The Catalpa Tree.

We notice that prominent railroad men are discussing the value of the catalpa tree for furnishing timber most suitable for railroad ties. We find in the *Railway Age* several letters, from which we make extracts to show the value of the wood to the mechanic and indirectly the advantage which it would be to our tree planters to grow it:

In the spring of 1871, in conversation with Wm. R. Arthur, formerly superintendent of the Illinois Central railroad, he stated that catalpa trees would last forever; that it was easily cultivated, was of rapid growth, and when planted in groves grew straight and tall as any forest tree; that he had several groves then growing on his farm that had been planted but four years and were 20 to 30 feet high; that he had planted them for fence posts, but had subsequently learned that they would hold a spike as well as oak and would not split. Hence their value for cross-ties.

Three years ago I cut from a catalpa tree, that had been cut down after growing 30 years as a shade tree, two railroad cross-ties, and placed them in a track over which trains pass every hour, one under a rail joint. The spikes show no signs of loosening. The catalpa does not hold a spike as well as oak, but sufficiently well for all practical purposes. It does not split easily. While not as tough as some woods, it should not be termed brittle, as stated in Millikin's essay. I subjected pieces of catalpa, oak and ash, one inch square, to a breaking pressure twelve inches between supports. The catalpa broke under a pressure of 703 pounds; ash 890 pounds; one piece of oak at 577, one at 709, and one at 1,141 pounds. The catalpa deflected three times as much as the oak or ash before breaking.

This handsome and valuable tree is native in all the southwestern States, but is everywhere rare. It is distinguished by its silver-gray, slightly furrowed bark, its wide-spreading head, the fewness of its branches, and the fine, pale green of its very large heart-shaped leaves. It is a very profuse bloomer except in wet summers. The flowers are very showy, large, bell-shaped, white, slightly tinged with violet, and dotted with purple in the throat. They are succeeded by long bean-shaped seed pods, which hang till the next spring, when they open, and the small, thin, broadly-winged seeds are borne away on the winds. The "Farmers and Planters' Encyclopedia" says the rapid growth of the catalpa in almost every situation in which it can be placed in the Middle States, and the adaptation of its wood to fence posts and other useful purposes, make it deserving the attention of farmers. The wood, though light, is very compact, of fine texture, and susceptible of the most brilliant polish, its fine straw color producing a fine effect in cabinet work and inside finish for houses.

Those wishing to propagate the catalpa should gather the seed pods this or next month; put in a dry place secured from mice. They may be found hanging from the catalpa tree, planted as a shade tree in most of the cities and towns in Ohio. There are fifty or more seeds in each pod. Plant in spring, in good soil, in rows three or four feet apart, six inches in the row, and thin down to one foot. Keep the ground clean and let them grow three years; then transplant, placing them in rows ten feet apart north and south, and six feet apart east and west. In from six to eight years remove each alternate tree in rows running north and south for fence posts and telegraph poles, leaving the remaining trees ten feet apart one way and twelve the other, 363 to the acre. In from six to eight years more these will be large enough to make four to eight railroad ties each, if they have been planted in good ground. They should be split or sawed through the middle and the round side placed on the ground. The catalpa has only a film of sap one-sixteenth inch thick.

Each acre and a half of ground, thus planted and properly cared for, will furnish enough fence posts and telegraph poles in from eight to twelve years to pay for the land and all expense of planting, care and protection, and in from fifteen to eighteen years furnish railroad ties for one mile of track, which at fifty cents each (cheap considering their quality) will pay \$50 per year on each acre of ground for each year they have been growing. Can a farmer make a better investment for himself and family than to plant ten or twelve acres in catalpa trees? A railroad once tied with catalpa would find its annual expenses for repairs diminished \$200 per mile, a saving that would add 10% to the value of the property.

WALRUS-HIDE MACHINE BELTING.—The specimen of gigantic machine belting, says the *London Mining Journal*, which has recently attracted so much attention at the Leeds Corn Exchange, is manufactured by Mr. Joseph March, of that place, the material used being the skin of the walrus or sea horse. It is stated that this belting cannot be equaled by any yet introduced for strength and durability for heavy work when used upon large drums such as main driving. The thickness of the walrus hide is from one-half inch to one and one-quarter inch, so that belts of that substance can be made of all solid leather, and the fibers thereof being longer than any other hide used in strap

making, it is remarkably tough and lasting. There are walrus-hide belts in this country which are still running, and which have been in constant use as main driving belts in forges, saw-mills and other large works for 15, 18 and 20 years, yet they are in good running order, and giving the utmost satisfaction. It is frequently observed that in ordinary double belting a great strain takes place on the outside lap of the belt, which, of course, cannot be the case with the walrus-hide belt, owing to its being of one thickness only. It is remarked, moreover, that they run very slack, and do not require to be worked tight as some belts do; indeed, the bight on the drum is marvelous. For example, a 14-inch belt 90 feet long will drive 100-horse power with great ease. Mr. March is now having six 18-inch belts finished for a firm for main driving; they are made in lengths of from six feet to nine feet, the joints being cemented and put under great pressure for 48 hours, and then sewn with one-half inch laces one-eighth inch thick, and riveted with extra strong copper rivets, and the last joint when in use is made with steel plates and bolts. The price is lower than that of the best double belting, and the great drawback is that walrus hides are now and then very scarce and high in price; four years ago they were 5s 6d to 6s per pound in the rough, but there is now a better supply of them, though how long this will last cannot be determined.

Economy in Engine Wiping.

The *Railway Age* shows a point of economy in railway management. It says every railway company pays thousands of dollars annually for the mere service of cleaning and polishing its locomotives in order to make them look well. Is it not possible that this is a useless waste of money? The idea is a new one. We do not know that it has ever been suggested in print, but we do know that it is being seriously considered by one or two managers at least.

The superintendent of the Philadelphia and Reading railroad is the first, so far as we are informed, to put the idea to practical test. That great road employs 410 locomotive engines, and the superintendent estimates that by dispensing with wiping them, he is saving no less than \$235 a day, or say \$85,000 a year. If this has heretofore been a needless expense, what an immense amount of money has been thrown away by this company alone—how many millions have been wasted by the railways of the country!

The idea that locomotives must be showy as well as useful is almost peculiarly an American one. Every American traveler in Europe has been struck by the plainness of railway engines abroad—plain black, serviceable machines, without brass or gilt or polished steel ornaments, often with the machinery out of sight—ugly indeed as compared with our glittering engines, but splendid specimens of mechanical skill, and wonderful for power and speed. This idea of utility rather than beauty has been adopted in our own country of late years, and polished brass bands, gilt letters and showy stripes have given place to sober, hard-working black, requiring little labor for the sake of looks.

Injury from Manufactory Smoke.

It seems odd that, in a country like England, where bituminous coal smoke penetrates almost everywhere, any one should think of recovering damages on account of its deleterious effects. But it seems this has not only been attempted but actually done, as is shown by the following:

At the Stockport county court, Mr. Benjamin Whitman, nurseryman, Reddish, claimed from Mr. Obadiah Stafford, contractor, Guide Bridge, the sum of £20 for damage to plants caused by smoke from the engine of a mortar mill belonging to the defendant. The plaintiff's nurseries comprised forty-two acres of land, nine green-houses, and amongst other valuable stock over 20,000 camellias. The defendant, for the purpose of executing some contracts in the township of Reddish, had erected a mortar mill about 40 yards from the nurseries, and the smoke from the engine had destroyed a large number of plants, the damage being assessed at £81. Defendant denied that the damage was caused by the small quantity of smoke emitted from his six-horse engine, and attributed it to the railway traffic, the manufactories, and dwellings that have increased very rapidly in the district of late. The case was submitted to a jury and they gave a verdict for the plaintiff for £25 and costs.

GOOD HEALTH.

Dyspepsia.

The nervous energy is the motive power of the whole man, spiritual, mental and physical. When that power is equally distributed the body is well, the brain is clear and the heart is buoyant. If the brain has more than its share, it burns itself up, and makes the "lean Cassius,"—the restless body and the anxious countenance.

As there is a given quantity of nervous influence for the whole body, if the brain has more than its natural portion, the stomach has less, consequently the food is not thoroughly assimilated, or, as we call it, "digested." This being the case, the requisite amount of nutriment is not derived from the food, and the whole body suffers, doubly suffers; for not only is the sup-

ply of nutriment deficient, but the quality is imperfect. These things go on, aggravating each other, until there is not a sound spot in the whole body; the whole machinery of the man is by turns the seat of some ache or pain, or "symptom." This is a common form of aggravated dyspepsia.

Such being the facts, some useful practical lessons may be learned.

1. Never sit down to a table with an anxious or disturbed mind; better a hundred-fold intermit that meal, for there will then be that much more food in the world for hungrier stomachs than yours; and besides, eating under such circumstances can only, and will always, prolong and aggravate the condition of things.

2. Never sit down to a meal after any intense mental effort, for physical and mental injury is inevitable, and no man has a right deliberately to injure body, mind or estate.

3. Never go to a full table during bodily exhaustion; designated by some as being worn out, tired to death, used up, done over, and the like. The wisest thing you can do under such circumstances is to take a cracker and a cup of warm tea, either black or green, and no more. In ten minutes you will feel a degree of refreshment and liveliness which will be pleasantly surprising to you; not of the transient kind, which a glass of liquor affords, but permanent, for the tea gives present stimulus and a little strength, and, before it subsides, nutriment begins to be drawn from the sugar and cream and bread, thus allowing the body, gradually and by safe degrees, to regain its usual vigor. Then, in a couple of hours you may take a full meal, provided it does not bring it later than two hours before sundown; if later, then take nothing for that day, in addition to the cracker and tea, and the next day you will feel a freshness and vigor not recently known. No reader will require to be advised a second time, who will make a trial as above, while it is a fact of no unusual observation among intelligent physicians, that eating heartily, under bodily exhaustion, is not an infrequent cause of alarming and painful illness, and sometimes of sudden death. These things being so, let every family make it a point to assemble around the family board with kindly feelings, with a cheerful humor and a courteous spirit; and let that member be sent from the table in disgrace, who presumes to mar the ought-to-be blest reunion, by sullen silence, or impatient look, or angry tone, or complaining tongue. Eat in thankful gladness, or away with you to the kitchen, you graceless churl, you ungrateful, pestilent lout that you are. There was grand and good philosophy in the old time custom of having a buf-foon, or music, at the dinner-table.—*Hall's Journal of Health.*

Carpets and Disease.

Is it true that carpets are a fruitful source of disease? that organic particles from the sick become entangled in them?

We answer emphatically, yes, and we quote Prof. Tyndall, in "Fragments of Science," who says, in regard to a case of scarlatina of apparently spontaneous origin: "But then the question arose, how did the young lady catch scarlatina? She had come there on a visit two months previously, and it was only after she had been a month in the house that she was taken ill. The housekeeper at once cleared up the mystery. The young lady, on her arrival, had expressed a wish to occupy a nice room in an isolated tower; and in this room six months previously a visitor had been confined with an attack of scarlatina. The room had been swept and whitewashed, but the carpets had been permitted to remain. This is one case in many. So long as the seeds of disease are kept alive epidemics must occur, and so long as certain habits and customs prevail, then seeds must be kept alive. Imperfect sewerage, unrenovated walls, uncleaned floors and carpets, are among the leading causes of retained disease.

Sewerage in these days is receiving a fair share of public and private attention, and the walls of houses, where contagious diseases have been, are very generally cleaned, whitewashed or newly papered; but carpets are too often overlooked as the carrier of disease. The truth is that they, more than any article of furniture, more even than the walls of the room, gather and retain dust; and this dust, though chiefly inorganic, and comparatively harmless, contains organic germs, which only need to be raised into the air and taken into the human economy to develop into active disease; creating, under favorable circumstances, an epidemic.

Do we believe this? Any careful physician or nurse knows that it is true. Again, the dust, which we spoke of as "comparatively harmless," is a most fruitful source of catarrh and consumption. The irritation of the mucous membrane of the nose, throat and lungs, becoming chronic, leads to serious disease, that undermines health and destroys life. Can we deny this?

Again, how many women say: "If it were not for the sweeping of my carpets I could get along with housekeeping very well." Many women know from experience that sweeping is one of the great trials of the housekeeper's life; and that it causes much of "the weakness" among women.

"Fore-warned is fore-armed." When we see the need of change in any direction we are ready to accept the better methods. What shall these better methods be in relation to carpets and disease?—*Herald of Health.*

THE ORIGINAL ARTICLES in this paper are mostly set in solid type, giving in our columns one-third more reading than is contained in ordinary leaded matter.

Address all letters to the firm, and not to individual members, or others, who may at any time be absent.

Our latest forms go to press on Thursday evening.

SAN FRANCISCO:

Saturday Morning, Jan. 13, 1876.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Improved Concentrating Tables; The Lick Estate; Items of Interest from the Mines; Portable Engines; Volcanite, 17. Tax on Incorporations; Working Deep Diggings; The Public Health, 24. The Silver Mines of Jefferson City and Boulder, M. T., 24-25. Mechanical Ore Concentration and Separation, 17. 25. The Bonanza, 28.

ILLUSTRATIONS.—Tolles's Improved Concentrating Tables, 17. Moonlight on the Susquehanna, 22. Howland's Rotary Quartz Mill, 25.

MECHANICAL PROGRESS.—New Rock Crusher; The Swiss Engine at American Progress; Another Note on Tempering; A New Fire Escape; Petroleum in Metal Working; American Wall Paper, 19.

SCIENTIFIC PROGRESS.—Inventors Should Study Science; Oil from Wood; Quicksilver Fire Alarm; The Latest Arctic Expedition; Mine Signals; Siphon; Pipes as Electric Distributors, 19.

USEFUL INFORMATION.—The Catalpa Tree; Walrus-Hide Machine Belting; Economy in Engine Wiping; Injury from Manufacture Smoke, 23.

GOOD HEALTH.—Dyspepsia; Carps and Disease, 23.

THE ENGINEER.—The New York and Long Island Bridge; Hydraulic Propulsion of Tramway Cars; Engineering Items; The Great Mexican Railway; The Paris Buildings; Ferro-Railway, 23.

MINING SUMMARY from the various counties in California, Colorado, Montana, Nevada and Idaho, 21-23.

GENERAL NEWS ITEMS on page 29 and other pages.

MISCELLANEOUS.—Review of the Pig Iron Market; The Salinas Quicksilver Mine; A Rich Country; Mining in Arizona; Royal Ray to Find Rich Mines; Mining Outlook in Calaveras, 13. Moonlight on the Susquehanna; Drying Apparatus; The American Mine; Cost of Engines for Armor-Clad Ships of War; The Isthmus Canal; Construction of the Hoof; Sonoma Coal; A New Solvent for Copal, 22. San Benito County Mines, 23. Death of Commodore Vanderbilt; Manganese Ores of Butte, 26.

NEW ADVERTISEMENTS.

Steam Engines, Baker & Hamilton, S. F.; Dividend Notices—German Savings and Loan Society, Geo. Lette, Sec'y.; San Francisco Savings Union, Lovell White, Sec'y.; Mining Sale—Josephine Gravel Mining Co., Wm. Small, Sec'y. Assessment Notices—Howland Tunnel Co., J. M. Haven, Sec'y.; Aetna Tunnel Co., J. M. Haven, Sec'y.

TAX ON INCORPORATIONS.—The proposition now pending for licensing professions, companies, etc., not heretofore taking out licenses, is creating quite a stir in this city. The tax on incorporations, if adopted, will yield no inconsiderable revenue. Any company doing business in this city, either in mines or mining, telegraphing, furnishing gas or water, depositories of treasure, money or other valuables, whose gross receipts are less than \$2,500 per month, \$10 per quarter; less than \$10,000, \$25; less than \$20,000, \$45; less than \$30,000, \$60; less than \$50,000, \$125; less than \$75,000, \$200; less than \$100,000, \$300 per quarter; more than \$100,000 and less than \$500,000, \$400 per quarter; over \$500,000, \$500. Under these two latter heads will come the principal banks, mining companies, gas and water companies, real estate associates, and other corporations doing a large business. Another section is as follows: Each person, firm or corporation liable to procure a license shall, upon application for a license, render to the license collector a sworn statement of the amount of business done and transacted by such firm or corporation during the preceding quarter, which statement shall determine and be the rate at which the license shall be issued for the succeeding quarter.

BULLION SHIPMENTS.—Since our last issue shipments from the prominent mines have been as follows: Modoc, January 3d, \$11,280; Washington, 3d, 293 ounces bullion; Northern Belle, 3d, \$10,337.60; K. K. Con, 2d, \$5,000; total for December, \$60,000; Tybo Con., December 31st, \$9,276.27—total for date, \$69,299.77; Con. Virginia, 5th, \$99,711.39—total for December account, \$357,716.87; California, 5th, 22 bars, \$92,151.19—total to date, \$889,784.82; Northern Belle, 5th, \$9,797.09; Modoc, 5th, \$5,600—total to date, \$53,200; Gila, 4th, \$9,806; Leopard, 3d, \$4,152.51; Belcher—total for December, \$112,000; Manhattan, 6th, \$13,100; Modoc, 7th, \$11,500—total to date, \$46,700.

Working Deep Diggings.

In almost every mining country, and especially on the Pacific coast, there are extensive beds of auriferous earth, sand and gravel that have not heretofore been made available simply because no efficient system and apparatus have been devised for working them economically. In many instances the upper strata of earth have been worked off to a considerable depth, at a fair profit, by existing imperfect methods and devices, but the expense of handling, removing and washing the material at a greater depth became so expensive that the mines were abandoned, even in the face of the well-known fact that the richest deposit of gold is found in the stratum nearest the bedrock. Although it has been suggested that earth, sand and gravel could be raised through a pipe or tube by means of hydraulic force, up to the time of the experiments of Geo. W. Cranston, of this city, the plans and apparatus suggested were incompetent to accomplish the object. The method recently patented through our agency by this gentleman not only consists in providing an improved arrangement, by which he is able to raise the auriferous material to the required height by means of hydraulic force, but also in a combination of apparatus by which he accomplishes the separation of the gold from the earthy matter, all by means of one continuous operation.

He first excavates at some place on the surface of the gravel bed a depression in which to locate the machine, so a sluice can easily be constructed away from the points where the earth is being taken out, which will convey the auriferous material to the machine. The improved machine consists of a ground pipe, which is composed of two or more sections, a sluice, a grizzly, regulating gate, elevating spout, flume, pipe and nozzle, etc. The two ground sections are preferably in two sections—or in one longitudinal section if desired—but in either case the sections are made in two halves. Each half is provided with a flange along each side, so that when the upper half is placed upon the lower half, the two can be permanently fastened together by bolting the flanges together. By this means the lower half, upon which the greatest wear comes, can be renewed without renewing the upper half.

One section is bent upward with a gradual curve towards the ends opposite the attachment of the other section, and the lower end of the spout is secured to its upward bent end. These sections are made of cast-iron, but the spout is made of wood. This spout can be of any desired length, according to the height it is required to raise the material from the excavation. The flume is attached to the upper end of the spout and is supported at an inclination downward, so that the water and material raised through the spout will be carried down through the flume. This flume can be made of any desired length, and is provided with riffles like an ordinary mining flume, so that the gold in the material raised will be caught in the flume.

A hydraulic pipe leads from some elevated water source or reservoir, and has a nozzle which passes at an angle through the top of the ground section and into the interior of the section so as to terminate at or near its center, the nozzle being pointed towards the wooden spout. The water coming through the hydraulic pipe with a velocity and pressure in proportion to the head or fall, will drive through the ground sections and up through the wooden pipe and thence be carried off down the flume. It is evident, therefore, that this stream of water will draw into it by suction and carry along with it by force any material, such as earth, sand, gravel or even large stones, that may be introduced into the rear end of the ground section, upon the well-known injector principle.

The other section is preferably an elbow, and this elbow is attached to the rear end of the ground section by a swivel joint, so that it can stand at any desired angle to the ground section, to conform to the inequality upon which it will rest, or it can be turned entirely round, as desired.

By means of this elbow or bent section, a hole can also be excavated by standing the ground section upon end, so that it will rest upon the elbow. A stream of water is then driven through the ground section and spout, by means of which the earth, gravel and water directly around the lower end of the elbow is drawn into the stream and carried up the spout. By rotating the elbow when in this position it is possible to sink a well or accomplish the work known to miners as "bottoming," with great speed.

Between the lower end of the sluice and the elbow, is constructed a one-sided box, in which is placed the "grizzly" or grating, so that the water and material from the diggings will pass over and through the "grizzly" before it enters the elbow. A gate is arranged to slide up and down between the "grizzly" and elbow, so that the inflow of water and material into the elbow can be regulated, but will be more frequently used as a valve to close the space above the incoming stream and thus prevent the entrance of air into the elbow with the water and material, as a free entrance of air with the material, behind the nozzle, creates "foaming" and impairs the force of the stream.

The auriferous material thrown into the sluice

will be carried down it and over the "grizzly," thus separating the large stones and allowing only the finer portion—in which the particles of gold are held—to pass through and go to the stream. The "grizzly" is constructed on an incline, towards the sideless side of the box, so that the large stones that cannot pass through will roll off to one side out of the way. To prevent the elbow from being clogged by the material, a branch pipe or tube is led from the hydraulic pipe and introduced into the bend of the elbow and directed towards the nozzle. This pipe will carry a small stream of water and will not only serve to keep the elbow clear but will materially assist the suction in forcing the material into the main stream.

The ground section, where the nozzle enters it, is made larger than the other section, so as to form an interior chamber around and in front of the nozzle of sufficient area to admit the material on all sides of the stream and nozzle. This interior chamber gradually contracts towards the section, until the passage corresponds with the passage in that section, thus giving a gradually decreasing space on all sides of the stream and nozzle, which the material will fill and be subject to the suction of the stream, and the incoming material at the rear will force the material in this chamber into the stream, thus giving the most positive action.

It will be evident from the above description, that the greatest amount of wear upon the sections and spout will be upon the bottoms of the sections, and to be able to renew this portion of the pipes economically, is one of the objects in making them in halves, so that the lower section can be replaced when it is worn out; but wearing plates or false bottoms could be applied if desired. A very economical plan would be to cast the lower halves of the sections with a longitudinal recess and fill this recess with wooden blocks, which would receive the wear.

This inventor is perfectly aware that it has been attempted to raise tailings from excavations in mines by placing a straight box or spout against the bank and introducing the hydraulic nozzle into its lower end, so as to lift the material directly in a straight line. This, however, is extremely difficult to do. It requires the sweep of a curve at the lower end of the spout, so that the material to be lifted will be thoroughly mingled and in moving action with the water before the upward motion is given. Mr. Cranston's combination of a gold-saving flume with the spout enables him to accomplish at a single operation and with the same stream of water, both the raising of the material and the separation of the gold and heavy metals, thus rendering the process economical, simple and complete.

Public Health.

In comparison with several of the years last past the death rate in this city is alarming, and it is feared that if the present dry weather continues, a still further proportionate increase may be expected. The epidemic of small-pox, which has prevailed for some months in San Francisco, has of course materially increased the death rate, and now for some time the equally, if not more, dangerous diphtheria is committing its ravages. This is by no means confined to the city, as it extends all over the coast, varying, however, in degree in different localities. This scourge is principally confined to the little folks and is not considered dangerous to grown persons. Throat affections of different kinds are prevalent, however, among grown people also.

Diphtheria has now become so dangerous to children that parents all over the coast are greatly alarmed and every remedy is tried. No specific has yet been found, however, and physicians disagree as to cause as well as to treatment. Although this is no uncommon circumstance, the treatment varies so greatly that the opinion prevails that the profession knows less about the disease than its importance warrants. To many diphtheria is more alarming than small-pox itself, usually considered the most disagreeable and dangerous of diseases. For it, however, vaccination furnishes a preventive; for diphtheria there seems to be none, and what is worse, the chances appear less favorable for recovery from the former than the latter.

In some families as many as four, five or six children have been taken away in the space of two weeks. Every precaution is taken by careful parents to prevent catching the disease, but it appears to be in the form of an epidemic and one which the physicians are unable to check. The old theory that it owes its cause to defective sewage seems exploded, as it appears in all localities, whether well sewered or not; and the interior parts of the State are by no means free from it. Of course the ravages are more apparent in the city, owing to the density of population.

It is hoped that after a few good rains the epidemic will cease, though no medical expert has publicly given any reason for the expectation. The ravages now being committed by diphtheria are such as to call to it the most searching and scientific attention of the medical profession, for unless some sovereign remedy is discovered and applied it will doubtless continue, periodically at least, to decimate the ranks of the children of this coast. The public naturally look to the physicians for aid, but in this case, sad to say, the profession seems deficient, and the societies throughout the country should give the disease the most unceasing attention in order to discover a remedy.

The Silver Mines of Jefferson City and Boulder, M. T.

EDITORS PRESS:—The mining of this portion of Jefferson county is confined at present principally to two districts, the Colorado and the Boulder—distant from Helena from 20 to 30 miles. A few mines in these districts have been sufficiently developed to establish for each a character for richness as well as for stability and permanence, giving as far as opened the characteristics of true fissure veins and likely to hold out as greater depth is attained.

The leading mine in Colorado district, and ranking among the best in the Territory is

The Consolidated Gregory.

It is located within four miles of Jefferson City, and worked by an incorporated company, Seligman & Co., of New York, as also of your city, being among the number of the principal stockholders.

Besides much work previously done it has been steadily and profitably mined since it became the property of the company. The mine is opened by one main shaft to the depth of 170 feet, by a tunnel 525 feet, and by two levels east of the shaft 250 feet each, with one on the west of 50 feet.

The average width of fissure is six feet, and the ore vein from 18 inches to two feet, widening in places to five feet, where the ore is usually purer than in the narrower portions. The walls are of trap, although granite seems to be the prevailing country rock of the neighborhood. They are smooth and beautiful, nearly perpendicular, with but a slight dip to the north, the direction of the lode being east and west. The character of ore is argentiferous galena, and shipments to New York averaged \$175 per ton in silver, and give from 60 to 65% in lead. The cost for freight to New York and for sacks is about \$54 per ton, leaving a good margin for profit.

The company shipped last year 550 tons, and had on hand about 150 tons, besides some 4,000 tons of concentrating ore, held for future treatment, and valued at from \$15 to \$25 per ton. New steam hoisting works will be erected the ensuing season, the water and ore being at present raised by a whim.

It is under the management of Mr. L. R. Nettre, a gentleman of much practical experience, besides having had the advantages of a good mining education at Freiberg, which may account for its systematic working, and to some extent perhaps for its success financially. The ore body is said to hold in quantity and richness as greater depth has been attained.

The Gregory (Proper).

And discovery claim, next adjoining on the east, although not as well developed, is thought by its friends as little inferior to its neighbor. One level, 300 feet, shaft 90 feet. Has yielded, working process, \$125 per ton, and from 50 to 65% lead.

The Nelson, a few thousand feet further east, is opened by two tunnels, one of 312 feet in length, and reaching a depth from the surface of 180 feet. The lode varies in width from 12 inches to four feet, and the ore samples on an average \$100 per ton.

The Belle, of Belleville, some distance south of the Gregory, has a fissure from six to eight feet and a vein of solid galena, worth, in silver, \$105 per ton.

The Montana Company.

Mr. P. M. Saunders, superintendent, is at present working on one of its lodes, the North Pacific, believed to be both valuable and promising, but the large

Concentrating and Reduction Works

Recently erected by the company are of such importance and magnitude as to require a description somewhat in detail.

The building for the concentrating works is 100 feet in length by 33 feet in width, and four stories high, besides having a tower of three stories, and is provided with a 60-horse engine and two 40-horse boilers for driving the machinery. The reduction works are also large and substantial. The amount of lumber used for both was 260,000 feet, 1,200 perch of stone, 150,000 brick and 15,000 fire-brick. The main stack 50 feet high and 36-inch flue. The ore is introduced from the ore shed on the hill in the rear to the fourth story, where it passes, first, through Blake's rock-breaker; second, into Krom's drying furnace, where it is kept in a constant motion, dropping slowly from shelf to shelf for 30 minutes, when it is thoroughly dried; third, into a set of Krom's rollers, similar to the Cornish, and thence into screens, where it is sized, the finest passing into an elevator, and the coarser into a pair of similar rolls to be further crushed before being carried to the elevator. It is then conducted to a bin, and afterwards weighed on a pair of Marvin scales.

It is now carried by a second elevator to the top of the tower (70 feet) and made to pass, on its way down, through four of Krom's patent revolving screens, for the purpose of sizing it.

The ore thus sized is passed through eight concentrators (Krom's) to the third floor, and from thence to the second floor to be re-concentrated through four concentrators. The

concentrated ore is roasted in Bruckner's cylinders and in two reverberatories, after which it is converted into base bullion by a water jacket smelter. All the dust of the works is collected by a Sturtevant exhaust fan and carried into bins outside of the building for treatment by Bruckner cylinders, and finally reduced by pan and settler process to bar silver. Daily capacity of concentrating works, 50 tons. The construction was committed to Mr. Rodgers, a gentleman thoroughly conversant with the Krom process, and sent out for the purpose, so that a full and fair test of its workings on the galena ores in this and surrounding districts may be expected to be made, and the question as to its merits, as compared with wet concentration, fully settled.

Drs. Parker & Brooks are running a tunnel with the view of tapping and working five parallel leads, 80 feet apart, the location being between the North Pacific or Argentinum mine and the concentrating works.

Wherever opened, as in many cases near the surface, well-defined veins of argentiferous galena make their appearance, the ores represented as giving sample assays from \$110 to \$340. The Silver Plate, adjoining the North Pacific on the east, is owned by Seales & Co. Shaft 120 feet; lode 5½ feet in width; 2½ feet of manganese, running from 80 to 95%, and most of remaining ledge matter made up of galena.

The Alta California, 3,000 feet east of the Argentinum. Incline 165 feet; 9 feet of galena, worth \$50 per ton silver and 27% lead; 2,200 feet owned by Col. J. A. Viall, of Helena.

The C. C. lode, A. Street owner, is said to be six feet from wall to wall; ores both milling and smelting, and giving some assays as high as \$250. Situated near the road from Jefferson City to the Gregory. The Byron, Paymaster, Gray Eagle and others in the same vicinity, are represented as more or less promising. Messrs. Sites & Duges, in addition to a quartz mine of milling and smelting ore, worth about \$50 per ton, have a very valuable gravel claim in Homestake gulch, five miles from Jefferson City, that pays \$30 to the man. The bank is 12 feet deep and is worked by hydraulic.

We pass next to

Boulder District.

Which can well boast of having some of the finest mines in the county; the lodes generally large, well defined, and yielding ore in considerable quantity, and some of it of very high grade. The two at present attracting most attention are the

Rumley and Comet,

Lying like twins, side by side. It is to be hoped that they may ever thus lie lovingly in each other's embrace, drawing a wise lesson from the history of Esau and Jacob.

The Rumley, Mr. I. I. Lewis, superintendent, has a discovery shaft 90 feet, a shaft on claim No. 1, of 180 feet, and on claim No. 2 of 52 feet. A tunnel to strike No. 1 at the bottom of shaft and the discovery at 200 feet below surface, has been extended 390 feet, showing a stratum of galena from three to five feet, the whole carrying metal of more or less value. There is also a level on No. 1, east and west 190 feet. The ore thus far shipped has run from 70 to 190 ounces, equivalent at current rates to from \$85 to \$240 per ton. The vein lies wholly in the granite, giving evidence of increasing value as well as of permanence. The

Utsch Automatic Jig

Has been tried with success on the ores of this mine by A. M. Hatter & Bro., of Helena, who have recently introduced the invention, holding the right for the Territory. It is said to have a capacity for concentrating 50 tons in 10 hours, and separating as many of the different minerals as may be desired, providing their specific gravities are sufficiently distinct. The whole work is done in one operation, needing but rarely any human intervention.

The Comet mine

G. B. Russell, manager, is opened by tunnel 300 feet; shaft 70 feet; greatest depth from surface 90 feet. Lode averaging 8 feet, in some parts having 14 feet of solid argentiferous galena, that runs \$70 per ton for the whole vein. First class ore gives \$150 in silver and sometimes as high as 75% lead—50% being a fair average for the whole. One thousand of first class were shipped the past year, and there are now nearly 4,000 tons on the dumps. As those most interested were awaiting the returns of about \$20,000 worth of ore, at the time, in the market, they may be excused for being a little jubilant. Finer walls one could not wish to see, and a more suitable width of lode for convenient working is seldom found.

The Molly McGregor,

One mile south, has produced some of the finest smelting ore in the district, and its future is looked upon by its friends as exceedingly flattering. Shaft 75 feet—seven feet between walls, averaging two feet of galena.

The Australia,

Three-fourths of a mile east of the Rumley & Comet, and on the same belt, has a discovery

shaft 34 feet, from which 63 tons paid \$170 each. A tunnel is being run to tap lode at the depth of 250 feet, now, within 50 feet of vein, which has a slight dip to the north. There is also a shaft 100 feet deep on the same lode, 800 feet west, which shows five feet of solid ore, thought to average \$60 per ton.

About two miles further east, on the same range, there are several locations.

The Yellow Jacket,

Owned by Messrs. Jones, Rice & Co., is opened by two shafts, 34 and 48 feet, and drift from the foot of one of them has been run the distance of 50 or more feet across the lodes, passing all the way through ledge matter, finding a body of argentiferous galena and oxides, at least 15 feet in width, estimated to average \$30 per ton in silver, saying nothing of the lead.

On the authority of Mr. Jones, one of the principal owners, and also on that of a gentleman of standing who assayed it, ore taken from different portions of the mine runs from \$40 to

The Stock Boards.

The annual meetings of the San Francisco and Pacific Stock and Exchange Boards took place this week. The election of the San Francisco Board resulted as follows: President, John W. Coleman (re-elected); Vice-President, C. W. Bonyage (re-elected); Chairman, B. H. Coit, (re-elected); Treasurer, H. Schmiedell (re-elected).

President John W. Coleman made an extended report, embracing partially the increase of the business from the organization of the Board up to the present time. We shall refer more fully to this address in an "Annual Review" next week.

The annual meeting of the Pacific Stock Exchange was held on Tuesday and the following officers were elected: E. J. Baldwin, President; C. L. Weller, Vice-President; A. J. Moulder, Secretary; J. Tilden, Chairman; G. C. Hickox, Treasurer; T. C. Van Ness, William H. Wright and Paul F. Beardsley, Trust Fund Committee. Mr.

(Copyrighted.)

Mechanical Ore Concentration and Separation—No 17.

(Written for the PRESS by FRANCIS M. F. CAZIN, M. E., Santa Fe, New Mexico.)

Stamps and Pulverizers.

Before continuing further with the department of the subject under consideration in the last article, a further notice of crushing and pulverizing machinery is necessary, although this more properly belonged to a portion printed in an early part of the treatise:

If of anything, the "Great West" may boast of multiplicity and variety of stamps; but with all that it remains a fact that stamps constitute the least economical and the least rational as well as the most clumsy and the most awkward contrivance for ore breaking. What crusher

and roller can do, therefore, should never be attempted by stamps. Among all the different patterns in use of late, the introduction of stamps deprived of the feature of cams have been tried. They differ only in the motion, but not in the effect of the blow, from older patterns. The so-called steam stamps have a steam cylinder and pitman to each head. The "atmospheric stamps" move by a curved shaft and have air cylinders to temper the blow.

Howland's rotary pulverizing and amalgamating quartz mill (illustrated herewith) will be found to answer all purposes best where stamp mills will be needed, for a reserve action in mineral dressing, and possesses many advantages which others do not, of which not the least is that its work is reduced to a rotary motion in a higher degree than with any other kind of stamp mill.

Pulverizers, whether on the ball or burr principle, do not do the kind of work required for concentration, because they equalize the shape of particles too much and destroy a quality (cleavage) which has to assist in concentrating sizes of very small dimension.

Wet or Dry Breaking.

Whether it will be more advantageous to crush, roll or stamp dry or wet for the purpose of mineral dressing, must be decided entirely by local circumstances.

Unless the ore, when brought to the crusher, be at least dry enough with the assistance of the dust produced by the crushing itself, not to clog, it would be advisable to add water, but if the ore is not clayish or of a clogging nature, dry crushing is preferable, and the same is the case for rollers. All the sizing which should be done between crusher and rollers, so as to withdraw from further action what does not require it, and also all sizing after rolling, so as to retain what requires further breaking, can be done dry, and is indeed done dry with better advantage.

The further particulars concerning sizes will be determined on in the following section.

LIFE OF GENERAL CUSTER.—A very interesting book entitled, "The Life of Major-General George A. Custer," has been compiled by Captain Frederick Whittaker, and is for sale for \$4.50 by A. Roman & Co., in this city. The work is a very interesting and exciting one, and describes in a vivid manner the numerous daring exploits of the "gallant Custer." It gives a complete history of his life from his boyhood, with a detailed account of his fighting during the civil war, and also of the Indian campaigns, in the last of which he lost his life, fighting to the last. The portrait drawn seems like that of a knight of romance, and after reading the history of this dashing soldier one feels inclined to take him as an ideal hero. He is so looked upon by thousands in the nation for which he fought and died, and a history of this brave young officer should be on the shelves of all who admire patriotism, bravery, skill and other qualities which go to make a successful soldier. The book is well illustrated and comprises about 650 pages.

DESERT LANDS.—A dispatch from Washington says: "House reported a bill for the sale of desert lands in California, Oregon, Nevada and the Territories. It provides for the filing of a declaration with a register and receiver of a land district in which the desert lands are situated, that the persons intend to reclaim the tract of desert lands, not exceeding one section, by conducting water upon the same within periods of three years thereafter, and upon subsequent proof of such reclamation and payment of \$1.25 per acre for such tract, a patent therefor shall be issued. All mineral and timber lands are excluded. Lands that will not, without irrigation, produce some agricultural crop, are to be deemed desert lands. The bill was passed."

HOWLAND'S ROTARY QUARTZ MILL.

\$150 by assay. The indications on the surface are excellent, and a depth of 200 feet will probably reach a rich chimney. The same parties own two other claims on the same lodes.

In the same neighborhood is the Virginia Belle, owned by Dr. Brooke and Mr. B. P. Mason, incline 40 feet, crevice 8 feet, vein of galena 3 feet; ore sold as high as \$122 per ton, pronounced by some to be a true contact vein, as it has granite on one wall and either porphyry or trape for the other. The Paul Jones is similar in character. The Amazon, the Emmett, the Spencer, in this locality are said to be looking well, as also the Bismarck, Terre Haute, Silver Gem and others in other portions of the district.

MEXICAN CONSUL PRITCHARD regards the filibustering talk as of sufficient importance to justify him in addressing an official letter to Governor Irwin calling attention to the startling condition of society on the frontier of Lower California, and asking for the preservation of peace.

Baldwin congratulated the Exchange on its success during the past year—during which time sales of stock to the amount of \$125,000,000 have been made—and predicted even brighter fortunes in the future. He pledged his hearty co-operation and earnest efforts to advance the interests of the Exchange. Financially the institution has been a great success, having paid to each member during the year 1876 dividends to the amount of \$1,800.

ALTHOUGH a great many men are preparing to go to the Black hills in the spring, the fact is there are just as many men who are willing to swear positively that the Black hills country is the worst place a man can go, as there are those who are lauding it up to the skies.

AN action has been commenced in the District Court at Salt Lake between A. G. Hunter and J. N. H. Patrick, to determine who is the rightful manager of the Flagstaff mine, Little Cottonwood, owned by an English company.

THE ENGINEER.

The New York and Long Island Bridge.

The plans of the bridge which is to be built across the East river from New York to Blackwell's island, and thence to Long island, says the *Iron Age*, are completed, and have been sent to the Board of Consulting Engineers—General Bernard, General Gilmore and O. Chanute. Plans were designed by 40 competitors from all over the country and from Canada, and the most feasible and inexpensive design will be adopted. The plan selected by them will be considered afterward by the directors. A prize of \$1,000 will be given for the best plan, \$500 for the second, and \$250 for the third in merit. It is the intention to afford, through the bridge, quick and direct communication with the center of Brooklyn. The bridge will be erected at Seventy-seventh street, and although the present charter only allows it to begin its approach at Third avenue, arrangements are being made to extend it to Fourth avenue, thus connecting with the rapid transit trains of the Harlem railroad. From this point the approach will ascend until it reaches Third avenue, where it will be 15 feet high, so as to reach the proposed line of rapid transit along that avenue. It will then be carried over to Blackwell's island, and from there to Long island, the height at that point being 150 feet. The route will be along Graham avenue, the foot of the bridge being at Woodside. A steam railroad will run the whole length of the bridge. From Fourth avenue to the river two tracks will be laid, and over the two spans, one 600 and the other 700 feet long, there will be only one track. Over Blackwell's island and along the route to Long island there will be a double track, having its terminus at Woodside, where it will connect with the Long island railroad. The distance between this railroad and the South Side railroad at that point is less than a mile and a half. A connection will be made with the latter railroad, which runs to Brooklyn, and thus a direct communication will be had between Yorkville and Brooklyn. The extent of the route will not exceed seven miles, and it is proposed to run the distance in 29 minutes. As soon as the plans are decided upon by the Board of Consulting Engineers, it is the intention of the directors to have the work begun as speedily as possible, and have it completed in two years. The cost, it is stated, will probably not exceed \$2,000,000.

HYDRAULIC PROPULSION OF TRAMWAY CARS.—About midway on a line or network of tramways, or at any other point of the same line, a motive-power engine is, according to the invention of Mr. L. Rousseau, C. E., of Brussels, mounted and arranged in combination with pumps and apparatus in a similar manner to those employed in ports, docks or warehouses, where the lifting apparatus are actuated by hydraulic pressure. For this purpose a pipe or tube for conducting water under pressure is laid down along the whole of the line of tramway or its branches, and in communication with a reservoir or receiver. At suitable distances apart valves or taps are placed in the said pipe or tube in order to supply water under pressure to the carriages of the train, which are placed at certain stations in communication with the reservoir or receiver above mentioned. At these different points or stations each carriage completes or renews and stores away the necessary quantity of water under pressure which is required to enable it to act automatically in the distance comprised between two hydrants for taking in the water. In order to maintain the water under pressure stored in each carriage, a receiver is fixed either horizontally or vertically under the floor of the carriage. This receiver is composed of one or more cylindrical metallic vessels containing compressed air at high-pressure (from 20 to 30 atmospheres), according to the power required. The compressed air contained in each receiver acts by its elasticity similar to a spring, either direct or by means of a piston, on the water supply contained also in one or more cylindrical vessels. The water under pressure in the reservoirs or receivers puts in motion the mechanism, and thereby gives rotary movement to the wheels of the carriage. In order to put the mechanism in motion, an ordinary hydraulic capstan is employed, or the well-known multiple cylinder apparatus of Brotherhood or West, or the well-known cyclo-dynamic machines of Mathon, or any other suitable mechanism, in order to obtain the same result. —*Mining Journal*.

ENGINEERING ITEMS.—The East River bridge has now nine wire ropes in position stretched from the New York to the Brooklyn anchorage, over the two towers, preparatory to the construction of a foot-bridge and other facilities for putting together the cables. Chile has 1,000,000 acres under cultivation by irrigation, it being estimated that one-third of the value of the entire farming land of the republic is expended in the enterprise. Wherever irrigation has been introduced the land has increased in value threefold. —*Eng. News*.

The Great Mexican Railway.

The building of the great railway from Vera Cruz to the City of Mexico was a colossal feat in constructive engineering. The intervening country was superbly beautiful, and crossed at right angles by the great Sierra range, through which is one continued panorama of beauty.

The railway is 267½ miles long, has 18 lengthy tunnels, and many fine iron bridges. It cost the grand sum of 40,000,000 Mexican dollars; and is undoubtedly the finest constructed railway on the American continent.

The first 40 miles is straight, and on a gentle grade, rising slowly from the sea; then for a distance of 75 miles it crosses over three distinct ranges of mountains, each of which stand up like a colossal stair-case. This section is very crooked. Winding around the numerous canyons in the mountain, the train runs for many miles over the brink of precipices, almost perpendicular, 3,000 feet. The grades are 400 feet per mile; and the ordinary American locomotives find the greatest difficulty in crossing unencumbered. But the company use an English engine—known as the Fairlie patent—which carries ten loaded cars with ease. It is a double engine, or two engines connected, with their heads turned together, and 30-inch drivers.

At the west end of this division, which is at Boca del Monte, the road bed reaches its greatest elevation, which is 13,000 feet above the sea at Vera Cruz; from there it gradually declines through a continuation of broad valleys to the City of Mexico. These valleys are from three to 20 miles wide, entirely hemmed in with tall mountains. Every foot is irrigated, and in a thorough state of cultivation. —*St. Louis Railroad Journal*.

THE PARIS BUILDINGS.—Work on the buildings for the Paris exposition of 1878 is well under way. At the present time more than 500 laborers and artisans are busy on the Champ de Mars. It is intended to light the building by a monster light-house. Among the objects of interest will be international competitive concerts, a collection of coins, a number of models, and above all, the monster captive balloon. It will be 16 feet higher than the Arc de Triomphe. It will be strong enough to carry a railway locomotive and its driver; it will hold 50 persons at one time, and raise them to an elevation of more than 1,600 feet. It will be made of alternate layers of silk and india rubber, which will be joined together by more than three and one-half miles of cotton, and altogether about 21 miles of cotton will be used. The balloon will be held captive by cables capable of resisting a strain of 10,000 kilogrammes. The balloon itself will be strong enough to resist a typhoon. This, at least, is what the French papers tell us.

PERSIAN RAILWAY.—Since reversing his concessions to Baron Reuter, the Shah of Persia has thought better of it. We are informed that he has authorized the construction of a railroad six miles long to join the capital with a palace south of Teheran. It is to be hoped that this may be the forerunner of many other Persian railways, independent of any through routes that may be arranged eventually to shorten the distance in traveling from Europe to India.

Death of Commodore Vanderbilt.

Cornelius Vanderbilt died on Wednesday, January 3d, at his residence in New York. He was nearly six years older than the century, having been born May 27th, 1794. His birthplace was Staten island, within sight of which he passed his whole life, and accumulated, with possibly one exception, the largest fortune ever gathered by one man in America, as the result of his own efforts. Astor, Stewart and Vanderbilt were the three rich men of their time, and it has never been established which was the richest of the three. The former inherited a fortune and added to it, by the natural increase in the value of real estate in a growing city. Stewart and Vanderbilt were poor boys, and began life at the lowest round of the industrial ladder. It is recorded of Vanderbilt that he was averse to education, but had no difficulty in mastering the science of mathematics so far as it enters into ordinary business transactions. At 16 years of age he commenced business for himself on a sufficiently elevated plane to secure contemporaneous notice. At that age he became owner of a ferry boat, which he plied himself between Staten island and New York. Two years later he owned two boats and was captain of a third. The following year, being 19 years of age, he thought himself rich enough to take a wife and establish himself in business in New York. His accumulation at this period was not rapid but constant, and at 23 he was said to be worth \$9,000 and free from debt. About this time he formed a business connection with Thomas Gibbons, to build and run a steamboat between New York and New Brunswick, N. J. The steamboat built, Vanderbilt took command of her and removed his family to Brunswick, where his wife conducted a hotel with much profit to the twin. He continued in full control of the Gibbons line until 1829, and made it pay a yearly profit of \$40,000. Meanwhile Vanderbilt had leased the ferry between New York and Elizabethport, N. J., and everything he touched turned to gold. Between 1829, when he left Gibbons, and 1843, when he became interested in the Nicaragua route, he operated boats on the Hudson river,

on Long Island sound, on the Boston route, and on the Delaware, from Bordentown to Philadelphia. His favorite plan of operation was to build superior boats to those of the existing line, and run them in opposition until he drove the old line off or forced them to buy him off. In either case, he got the profits of the business for some years, either by virtue of a monopoly or ceasing to oppose a monopoly. In 1851 he commenced his great struggle with the "Pacific Mail" and "United States" companies for the California travel. He put three steamers on the Atlantic side and four on the Pacific, and for a time carried on a spirited opposition. Crossing the continent between Greytown on the Atlantic coast and San Juan del Sur on the Pacific, a distance of 700 miles was saved, which enabled him to beat the other line on time. A branch line from Greytown to New Orleans was a part of this enterprise. In 1853, while Vanderbilt was on a visit to Europe, C. K. Garrison and Charles Morgan managed to get control of a majority of the stock, and threw Vanderbilt out of the management. The latter then turned with his wonted energy against his former associates, and by putting on independent lines compelled them to surrender control. In 1856 William Walker, the Nicaragua filibuster, confiscated some of Vanderbilt's property, and dated his own ruin from that act. Vanderbilt, making common cause with Costa Rica, drove Walker out of the country. Soon after Vanderbilt withdrew from the California business, receiving a large subsidy as compensation. During his steamboat career Vanderbilt owned 21 steamers, 11 of which he built himself, and with steamboats his entire fleet numbered 66. He withdrew from this branch of the carrying traffic in 1864, with a fortune estimated at \$40,000,000. Long before this he had become interested in railroads, and to this branch he now directed his exclusive attention. He was a large owner in the New York and New Haven railroad, and in 1864 was said to be the sole owner of the Harlem railroad. Soon after, he secured a controlling interest in the Hudson River and New York Central railroads, and effected a consolidation of the two. In 1873 he made arrangements with the Lake Shore and Michigan Southern railroad by which that line was operated in conjunction with the New York Central; thus presenting a line 978 miles in length, with branches aggregating 2,128 miles, all under one management, and representing a value of \$140,000,000, half of which belonged to the Vanderbilt family.

If Cornelius Vanderbilt was not one of the best, he certainly was not one of the worst of the railroad magnates of this country. His management was always based upon the policy of giving the public something better than they had been having, and making money by so doing. He kept his contracts with the public and with business associates, and studied to benefit local interests. Though without the advantage of education in the schools, he became cultivated to a degree later in life, and had some pretensions to refined tastes. His illness has continued through several months, and several times he had been thought at the point of death. The event had been so long anticipated that it is not supposed it will produce any marked effect in business or financial circles in New York. His fortune is estimated at \$85,000,000.

MANGANESE ORES OF BUTTE.—When Mr. C. E. Kemp was in this city a few weeks ago he obtained from Mr. Farlin specimens amounting to several pounds of silver ore taken from the Travona lode, which were as near an average of the manganese ores as he could select. Though several of the pieces were rich in silver and would run considerably higher than the average it would in no way affect the object in view, which was to see if the silver in these ores could be amalgamated without roasting. The result of a trial test of two pounds of Travona ore gave 48 pennyweights of amalgam which yielded bullion 900 fine, to the amount of 196.67 grains, which is equal to 496.73 ounces per ton. The sample from which the test was made assayed 476.28 ozs. per ton, showing a saving by the test made, without roasting the ore, of 86% of the silver. Mr. Kemp thinks had he taken a little more time that he could readily have saved 90% of the silver. The process used in making the experiment was the same as will be used in the new mill of Mr. Davis, and as many of the finest leads in Butte are of this black manganese character, this news of the successful treatment of these ores by so simple a method will greatly enhance their value, and bring these mines once more into prominent notice. —*Butte (Montana) Miner*.

A COMPLIMENT.

PLAINSBURG, MERCED CO., CAL., June 22d, 1874.
DEWEY & CO.—Gentlemen: I herewith tender my grateful acknowledgments for the energy, promptness and efficiency which you have displayed in procuring my patent.

Although you were entire strangers to me when I first communicated with you, I soon felt satisfied you were gentlemen of integrity, and shall always be happy to represent you as such. Very truly yours,

H. W. RUCKER, M. D.

CAMPO, SAN DIEGO CO., CAL., July 3d, 1874.
MEERS, DEWEY & CO.—Gentlemen: To-day I received the patent and other papers of my animal trap, that you so successfully worked through the patent office for me, for which please accept my best wishes. The chances are that I will have another application for you to make for me before long. I am well satisfied with your manner of doing business, and I think inventors of this coast stand in their own light when they do not put their business into your hands. I remain yours truly,
A. M. GASS.

DEWEY & CO.

American & Foreign Patent Agents

OFFICE, 224 SANSOME STREET, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent Reissues taken out Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Baden, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Granada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule price for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) SOONER than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more correctly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing to them the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

Cor. Market & Fremont Sts., S. F.

THE O'HARRA,

CHLORIDIZING FURNACE

Guaranteed to Chloridize from 85 to 95 per cent. of any gold or silver ores that are not more profitable for smelting. Will also desulphurize ores and put them in proper shape for working in cupola furnaces.

Cost of Roasting and Chloridizing by this Process:

Two cords of wood at \$6.....\$12.00

Two firemen at \$4.....8.00

1,500 lbs of salt at 14c.....22.50

Wear of shoes and power.....1.50

Cost for 15 tons.....\$44.00

Cost for one ton.....2.93 1/2

In a furnace of three or four times this capacity the cost is decreased by 20 per cent.

The furnace is now working successfully at the Poe Consolidated Co.'s mines, in the Payvine District. For further information, apply to

D. J. O'HARRA,

Reno, Nevada.

LOOK

The Great Western Scroll Saw Co.'s new and improved \$5.00 Foot and Steam Power Scroll and Bracket Saw is the best one yet invented. With it men and boys are making from \$8 to \$10 per day. We will send you a Machine, six Saws, 15 Patterns and two feet of prepared wood, on receipt of \$5. Address,

GREAT WESTERN SCROLL SAW CO.,

Leavenworth, Kansas.

DEETKEN ROASTING FURNACE.

The CHEAPEST and MOST EFFICIENT furnace for GOLD, SILVER and COPPER ORES. Capacity of furnace from six to fifty tons per day.

Grass Valley, Cal.

PICKERING ENGINE GOVERNOR.

Vallejo Foundry, October 17th, 1876.

Messrs. NETLAN & YOUNG, San Francisco.

Agents "Pickering Governors."

Gents:—The 10 two-inch Improved Speed Adjusting Governors I bought of you this year for my patent Straw

Burning Threshing Engines give

splendid satisfaction. They far

surpass for regularity of speed

any Governor that I have ever

seen, and I have seen all the best

kinds; I have seen the main belt

fly off the pulley several times

this season while threshing, and

the engineer did not discover it,

so perfectly was the speed main-

tained, until he was told of it;

this I consider something won-

derful; I consider the Governor

absolutely perfect, so far as

speed is concerned. I bought

and put on to one of my engines

a Shive Governor, to see which

was the best, and after one

season's trial I have no hesita-

tion in saying they are as far

superior to the Shive or any other

Governor that I have seen or used,

as the Shive Governor is to the old Butterfly Valve Gov-

ernor. I wish you would send me the lowest price that

you can furnish 25 Governors for next season's engines.

Yours respectfully, I. L. HEALD.

The Ingersoll Rock Drill

Is Extensively Used in the East and

TAKES THE PLACE OF ALL OTHERS,

Wherever introduced, because it can be run with less

power, labor and repairs, and do more work than any

other Drill in the market. It has but few parts, is easily

handled, being light, and has AUTOMATIC FEED, which

saves labor. WE ASK FOR TRIAL AGAINST ANY

COMPETITOR. For particular information regarding

Drills or Air Compressors, send for circular to

bullion, consisting of five dore bars and valued at \$5,500, was made on the 5th inst.

GROOM DISTRICT.

WORK.—Pioche Record, Dec. 31: J. Baker Dennison, Superintendent of the Groom mining works, together with Con. Reilly, arrived in town Friday last. These gentlemen say that work is being done to have everything in active operation in a short time, and they are confident of the ultimate success of the camp. The rush to Resting Springs is pretty lively at present, many deeming that their fortunes lie there.

WARD DISTRICT.

THE MINES.—Pioche Record, Dec. 31: We interviewed one of the parties returning from Ward City yesterday, he informing us that it was snowing very heavy there when he left, but it gradually grew pleasanter after the Prairie ranch was reached. The winners of the law suit in the Paymaster mine have gone to San Francisco to have the mine incorporated. Some miners and coal-burners have been knocked off from the Martin White company, and a notice is posted up in the office of the company that no checks would be issued until further orders from San Francisco.

Colorado.

FAVORABLE.—Colorado Miner, Dec. 30: During the past week a number of the miners have been enjoying their annual holiday, but work has been kept up in all the mines, although in some instances with slightly reduced force, owing to the reason alluded to. From Democrat, Sherman, Brown, Republican and Leavenworth mountains reports continue highly favorable in respect both to quantity and quality of ore. The new year starts out most encouragingly for our staple production.

THE PELICAN MINE.—After steadily hammering and roasting away for two years upon silver ores, this successful silver mill requires a little repainting, and the proprietors have determined to give it a thorough overhauling. Workmen are busily engaged putting in new and massive foundations for the cylinders, building new furnaces and will have when the work is completed, one of the most solid and substantial mills in the State. C. Hanson is superintending the work, which will probably occupy six or eight weeks.

Idaho.

THE MINES.—Owyhee Avalanche, Jan. 6: Unless heavy falls of snow occur soon, the placer mining prospects for the coming season will be rather dubious. Pat White says he has been in this camp nearly 12 years and that he never saw richer rock than that taken from the Empire recently. The prospects of the Belle Peck are improving daily. The ledge at the bottom of the shaft, about 180 feet from the surface, which is being worked now is turning out splendid ore. Operations are being prosecuted with vigor, and plenty of gold bars will be turned out in the coming few months. We understand that Mr. Crutcher has retired from the superintendency of the South Chariot, and is succeeded by M. A. Baldwin, Esq., of the Golden Chariot. Simonds melted a bar of bullion yesterday from Belle Peck crushing. The value of the bar is \$5,501.81, the proportion of which in gold is \$3,081.17. The Potosi mine, near town, is turning out much richer rock than ever it did before.

Montana.

SILVER.—Butte Miner, Dec. 24: For various reasons since the setting in of winter weather, work at many of the leads which were being developed has been discontinued, and as this is the present condition with a majority of the most promising mines in the camp, only a limited report of them can now be made. At the La Plata work has continued uninterrupted, and this mine to day is making the best record in Butte, taking out a large quantity of high grade ore, which, under contract, is purchased for reduction at the Dexter mill. It is principally due to the high grade of the ore from this mine the fact of the heavy shipments of bullion lately made at this mill. At the Rainbow lead the claims lately purchased by Messrs. Walker Bros. are being developed by having shafts sunk upon them; the deepest is now 75 feet from the surface, but as so little has been done that will in any way show the true character of these mines, we will defer making a more extended notice until water has been reached and levels started at this depth to connect the shafts. Some little work continues upon the Burlington lead.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's office at San Francisco.

MONOCHEIFF M. Co.—January 5th. Location: Inyo county, Cal. Capital stock, \$10,000,000. Directors—John Hamill, James Morton, Louis Goldstone, A. Boqueraz and R. J. King.

PACIFIC COAST LAND CO.—January 6th. Directors—W. C. Burnett, D. W. Parkhurst, Samuel D. Miller, J. S. Lute. Capital stock, \$1,000,000, divided into 10,000 shares.

PACIFIC TRIP HAMMER BRICK CO.—January 6th. Object: To carry on a brick yard at Somerville, Contra Costa county, Calif. Capital stock, \$50,000. Directors—L. J. Craft, T. R. Porter, R. H. Newton, D. Schindler and D. M. Burns.

HENRIETTA M. Co.—January 8th. Location: Butte county, Cal. Capital stock, \$10,000,000. Directors—J. H. Ferguson, H. Newman, J. F. Atwill and H. R. West.

AURUM AND ARGENTUM M. Co.—January 8th. Location: Inyo county, Cal. Directors—R. M. Fryer, A. H. Winnup, E. C. Freeland, C. W. Smith, W. H. Smith, Joseph Perrin and Geo. Smith.

CLEAR CREEK G. M. Co.—January 9th. Location, California. Directors—Edmund Green, H. C. Bidwell, R. E. Brewster, Geo. M. Perline and L. A. Booth. Capital stock, \$5,000,000.

SILVER LAKE M. Co.—January 10th. Location: Douglas county, Nev. Capital stock, \$10,000,000. Directors—Joseph Clark, John Skae, Joel F. Lightner, George R. Wells and C. S. Frank.

THERE is talk of a contest over Vanderbilt's will. One legatee said that the relatives outside of William H. Vanderbilt's family would never let it stand as it is, unless he, William H. Vanderbilt, should avoid all causes of dispute by giving his less fortunate co-claimants liberal shares of the immense wealth left by the Commodore, which, under the will, he controls. The friends of the Commodore say William H. Vanderbilt is to carry out the plan of his father for the construction of a hospital or a home for the benefit of the employees of Vanderbilt's roads. It is also understood that the Commodore has placed a large sum in the hands of his eldest son to distribute among his most valued friends.

THE San Francisco Journal of Commerce of this week has a very comprehensive review of the commercial and industrial features of this coast for the past year. On the first page is given a very elaborate map of the coast, showing the timber, agricultural and mining regions. The annual number of this journal consists of eight large pages.

The Bonanza.**Product of the Consolidated Virginia Mine.**

The annual meeting of the Consolidated Virginia mining company was held on Thursday last, when the reports of officers were presented. As they give a comprehensive review of the operations of this celebrated mine for the year, we print them entire:

President's Report

To the Stockholders of the Consolidated Virginia Mining Company.—On the 27th day of April, 1876, Mr. Edward Barron, trustee and president of this company, resigned his position. The former secretary was elected to fill the vacancy, and A. W. Havens was elected secretary. As this report will be read by interested persons not reached by the local papers, I presume a brief history of the mine and statement of the bullion product will prove interesting. The company was organized on June 7th, 1867. The mine is located in Virginia City, State of Nevada, and embraces the Comstock lode to the extent of 710 feet. The company originally owned more ground, which was transferred to the California mining company in 1873, and seven-twelfths of one share of California mining company's stock was paid to each share of Consolidated Virginia as a stock dividend. Fifteen assessments were levied. No. 1 in April, 1869, No. 15, June 11th, 1873. Total amount of assessments, \$438,499.53.

The property came under the present management January 11th, 1872, at which time the present superintendent was elected, and systematic prospecting was commenced. The amount of assessments since collected is \$277,150.12. The first dividend was declared May 7th, 1874, and dividends to number thirty-two were continued to and including December, 1876.

The following statement shows the amount of bullion produced:

Year.	Gold.	Silver.	Total.
1873.....	\$314,983.68	\$331,293.49	\$646,277.17
1874.....	2,063,433.13	2,915,045.92	4,978,479.05
1875.....	7,035,206.54	9,182,183.22	16,217,389.76
1876.....	7,373,145.36	9,279,504.11	16,652,649.47
			\$69,002,110.45
Dividends paid.....			\$27,000,000.00

This capital stock of the company is now 540,000 shares of the par value of \$100 each. Each share has paid \$50 in dividends, besides the stock dividend of seven-twelfths of a share of California. Letters are frequently received at the office of the company from stockholders asking that dividends may be forwarded by mail or express. We cannot do this. Non-residents can draw on the Secretary through any bank or broker in the city. The Trustees have sometimes paid the dividend by overdrafts rather than force silver upon a weak or falling market. This will account for the item of interest in disbursements.

I respectfully call your attention to the reports of the Superintendent and Secretary, herewith submitted.

CHAS. H. FISH, President.

San Francisco, January 11th, 1877.

Superintendent's Report.

Mr. Chas. H. Fish, President Consolidated Virginia Mining Company—Dear Sir: The total quantity of ore which has been taken out from the Consolidated Virginia mine during the year ending at this date is 142,679 tons. There were remaining on hand in the ore house and at the mills at the beginning of the year, 2,988 tons. There have been reduced 145,466 tons, yielding bullion to the value of \$16,661,940.70; this yield being 73½ per cent. of the assay value of the ore—no deduction being made for wet ore. We have now in the ore houses and at the mills 200 tons, valued by assay at \$28,471. All of this ore has been extracted from the 1,300, 1,400, 1,500 and 1,550-foot levels of the mine.

Ore Body on the 1,400 Foot Level.

On the 1,400-foot level, on the south end of the ore body, a large quantity of ore yet remains in place, but its grade is too low to meet our present requirements and large dividends. In the northern end of this level there also remains in place a large quantity of rich ore. It is from this latter locality that all the floods of water have come into the mine, from which we have suffered so much hindrance in our operations; and by reason of this we have been compelled to work this portion of the level slowly and with great care. No ore has been taken out from this quarter since the last flow of water, which occurred some two months ago. Within the past few days work has been resumed here, and the pumps are now in condition and ready to control whatever water may be encountered, and we are not likely to be hindered from the same cause in the future.

An Unexplored Region—The 1,550-Foot Level

On the 1,550-foot level the southern portion of the mine remains unexplored. No work has been done in this quarter during the past year.

On the 1,550-foot level the ore is of better quality than on any of the levels above, and the width of the ore body is quite as great as on the 1,500-foot level. These facts give us assurance that the 1,650-foot level, now about to be opened, will prove to be of great value—quite as much so as the 1,550-foot level. The depth of the 1,650-foot level—that is the distance up to the 1,550-foot level—is really but 42 feet. That comparatively small depth of ground has yielded more ore, and of a better quality, than has been produced from any other level in the

mine. The main shaft has been sunk from the 1,500-foot level to the 1,550-foot level. The drift on the 1,550-foot level, which connects with the Gould & Curry mine, and through which ore has been transported to the Gould & Curry shaft, and through that shaft raised to the surface, has been undergoing repairs for the past month, and it will require three weeks more to complete them. In the meantime no ore can be raised through the Gould & Curry shaft. This suspension of taking out ore through this outlet has caused a great reduction in our receipts.

Below the 1,550-Foot Level.

With the exception of running the lateral drift on the 1,700-foot level, no work has been done in the mine below the 1,550-foot level. The deep winze spoken of in my last annual report as having been sunk 147 feet from this (1,550-foot) level, and as having passed all the way through and terminating in ore of a very high grade, is yet full of water and will remain so until the ore vein is reached by the 1,650-foot level drift coming from the C. & C. shaft. This joint drift is now in 555 feet from the shaft, and it will reach the ore body some time in the ensuing month. Connections will then be made with the winze spoken of above, as well as with the winze sunk from the same level in the California mine. These connections will be made as soon as possible, as but little ore can be extracted until they are made and a circulation of air is obtained. The drift would have been into the ledge five months ago, but for the large flow of water met with in sinking the C. & C. shaft, which has greatly prolonged the sinking of the shaft and consequently delayed the running of this drift and the opening and working of the lower levels.

The 1,500-foot level of the mine is connected with the C. & C. shaft by a large drift—well timbered and laid with a T-rail track—being a convenient thoroughfare through which the ore is transported to that shaft to be raised to the surface, and at the same time it gives admission to air for ventilation of the mine.

On the 1,700-Foot Level.

The drift running north on the 1,700-foot level, which at the date of my former report had advanced north 107 feet from the southern boundary of the mine, has been extended north 283 feet, making the whole distance run 390 feet. This drift lies east of the vein, and so far no cross-cuts have been made on this level. The progress of this drift has been much retarded by bad air and frequent floods of water coming from the Gould & Curry mine—causing the drift to cave—and filling it up at times for a long distance. These obstacles will all be overcome very soon, so that work can be resumed there, as the water has ceased to flow and the connections which will be made with the C. & C. shaft on the 1,650-foot level will ventilate this portion of the mine.

Several thousand feet of drifts have been run in and to the mine during the year, at a heavy expense which was unavoidable.

Average Yield of the Ore.

As shown by the production of the mine as stated above, the average yield of the ore has been \$114.50 per ton. This apparent yield is lessened by three important items of expense to which the bullion has unavoidably been subjected, namely: The transportation of the bullion, the local taxes on net proceeds—the State and county tax being one and ninety-five hundredths per cent. and the city tax one-half of one per cent.—and an unprecedentedly large discount on silver.

The C. & C. Shaft.

One year ago the C. & C. shaft had reached the depth of 940 feet. It is now down 25 feet below the 1,650-foot level, and the work of sinking is going on. In sinking this shaft we had to contend with a great inflowing of water, which has continued from two hundred feet from the surface down. This flow has ranged from 43 to 37 inches, miners' measure. All the appurtenances to this shaft, such as the main building, the ore houses, the hoisting and pumping machinery, the pumps, pump bobs, etc., are complete in every respect. Everything has been constructed on a scale and in a manner commensurate with the large future requirements of the two mines. The facilities for landing wood, timber and other mining supplies, and for shipping the ore raised through this shaft to mills, have been much improved on by the construction of a branch track from the Virginia and Truckee railroad, which passes on both the upper and the lower sides in close proximity to the works. The cost of the shaft and all its appurtenances, together with all the real estate acquired for the purposes of the shaft, amounts, up to this date, to \$820,000.

Hoisting Works and Other Machinery.

The Consolidated Virginia hoisting works, the engines, machinery, air compressors, etc. are all in perfect order. Protection against fire here, as well as at the C. & C. shaft, has been secured by a complete system of water pipes, hydrants and hose, with a plentiful supply of water under heavy pressure. The building, which at the time of my last annual report, was being constructed for an assay and bullion department, has been completed and has been equipped with all the requisite apparatus, fixtures, and materials for melting and assaying, and this work is now being done here for both the Consolidated Virginia and California mines. It has proved to be a successful and economical institution, and its capacity for assaying and melting is fully equal to what was predicted,

which was \$5,000,000 of bullion per month.

In conclusion, it gives me great pleasure to state that, as we are overcoming the disadvantages under which we have been laboring of late, and in view of the indications which we have before us in the mine, I believe that the incoming year will be one of great prosperity.

Very respectfully,

JAMES G. FAIR, Superintendent.

Virginia, Nev., Dec. 31st, 1876.

An inventory of the property at the Consolidated Virginia mining company which accompanies the superintendent's report, shows property worth \$399,904.59, the real estate, hoisting works and assay office and machinery being valued at \$336,000; coal and wood supplies, at \$49,128.44; supplies in store-room, \$9,533.79, and assay supplies, \$5,242.36. An inventory of the Consolidated Virginia and California joint shaft property shows a total value of \$394,331.98, of which \$325,000 is represented in hoisting works and machinery; \$61,346.81 in timber and coal supplies, and \$7,985.17 in supplies in the store-room.

Secretary's Report.

The meeting was a very stormy one, some of the stockholders finding great fault with the management. Mr. Mackey denied the use of the diamond drill anywhere below the 1,500-foot level. S. P. Dewey very vigorously opposed the present management. At times the disputes between Flood, Dewey, Mackey and others threatened to end in a manner which all would have afterwards regretted. Never has a meeting of a mining company taken place where there was so much excitement manifested. On the election taking place the old board was re-elected without change.

General News Items.

THE net gain in population of this city last year was 35,450, or about 30,000 less than in 1875.

It is reported that parties are in Washington from California whose object it is to institute a movement for the annexation of Lower California to the United States.

The bill admitting Utah into the union is now in the hands of the House Territorial Committee. The scheme of admission will bring the Mormon question into prominence.

The severity of the financial crisis in Russia is shown by the fact that the municipality of Odessa, one of the richest in Russia, is unable to pay the salaries of its officials.

THE Assistant Treasurer of the United States at Philadelphia has filed an answer to the Centennial Board of Finance, claiming for the Government payment in full of \$1,500,000 before stockholders are reimbursed.

OUR merchandise exports last year aggregated \$31,056,200, and our treasure exports \$49,757,800, making a total of \$80,814,000, which is the largest since the opening of the port, and the amount of treasure shipped is the heaviest in ten years.

A DISPATCH from Madrid states that the extradition treaty between Spain and the United States includes crimes committed in Cuba and other colonies. The relations between Washington and Madrid are very cordial in respect to claims connected with Cuba.

GREENBACKS are actually worth more than silver coin in San Francisco at the present time. Monday gold coin was sold as low as six and one-eighth per cent. premium for greenbacks. Only once before since 1862 has this low premium been reached, which was in November, 1873. This makes legal tenders worth nearly 94½ cents, or about one per cent. more than half dollars in the market.

WOODWARD'S GARDENS embraces an Aquarium, Museum, Art Gallery, Conservatories, Tropical Houses, Menagerie, Seal Ponds and Skating Rink.

Mining and Scientific Press Patent Agency.

THE MINING AND SCIENTIFIC PRESS PATENT AGENCY was established in 1860—the first west of the Rocky Mountains. It has kept step with the rapid march of mechanical improvements. The records in its archives, its constantly increasing library, the accumulation of information of special importance to our home inventors, and the experience of its proprietors in an extensive and long continued personal practice in patent business, affords them combined advantages greater than any other agents can possibly offer to Pacific Coast inventors. Circulars of advice, free.

Address,

DEWEY & CO.,

Publishers MINING AND SCIENTIFIC PRESS AND PACIFIC RURAL PRESS, 224 Sansome Street, S. F. A. T. DEWEY, GEO. H. STRONG, W. B. EWER, JNO. L. BOONE.

HAMILTON, N.Y., May 28th, 1876.

To Messrs. Dewey & Co., Patent Agents.

GENTLEMEN:—I write to acknowledge the receipt by express of the U. S. letters patent, on my invention for breech loading ordnance, and to tender you again my very sincere thanks for the careful attention you have bestowed upon my application since I first placed it in your hands, for the evident great interest you have manifested in it, and for the uniform patient and cheerful courtesy which has constantly marked your correspondence in reference to it. I have had some dealings with other agencies in the same line in times past, and I can assure you that my correspondence with yours has been more pleasant and satisfactory than with any others, and I shall always take great pleasure in recommending your agency to any and all my acquaintances without hesitation or reservation, as I should certainly prefer to entrust my own business in your hands should I have any to transact in the same line hereafter. Yours, etc., J. R. N. OWEN.

APPROPRIATION ABROAD.—We copy the following from the Mining and Monetary Gazette, of London, England: "We deemed it advisable, as affording valuable information to our readers, to publish in recent issues of The Gazette, the full text of the 'United States Mining Laws and Instructions,' by the Commissioner of General Land Office," taken from our talented contemporary, THE MINING AND SCIENTIFIC PRESS, of San Francisco. The documents have now been issued in a handsomely bound volume, by Messrs. Dewey & Co., the publishers of our transatlantic contemporary, and it will be found very useful to those already interested in American mines, and to others who may be tempted to embark in that enterprise in the States."

CANFO, SAN DIEGO CO., CAL., July 3d, 1874. MESSRS. DEWEY & CO.—Gentlemen: To-day I received the patent and other papers of my animal trap, that you so successfully worked through the patent office for me, for which please accept my best wishes. The chances are that I will have another application for you to make for me before long. I am well satisfied with your manner of doing business, and I think inventors of this coast stand in their own light when they do not put their business into your hands. I remain yours truly, A. M. GASS.

SCIENTIFIC PRESS.—As the old year is drawing to a close and the new is rapidly approaching, all our mining friends should subscribe for this scientific journal, especially devoted to their interests. It is a California enterprise, and compares favorably with similar organs of years more experience and age in the old countries.—Coffey Enterprise.

THE EXPLORERS', MINERS' AND METALLOGISTS' COMPANION.—Comprising a practical exposition of the various departments of exploration, mining, engineering, assaying and metallurgy; containing 672 pages and 83 engravings. By J. S. Phillips, M. E. Price—cloth, \$10.50; in leather, \$12; postage 50 cts. Sold at this office.

ROASTING OF GOLD AND SILVER ORES, and the Extraction of their Respective Metals without Quicksilver, 1876. It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus. Price \$2.50 coin, or \$3 currency, postage free. Published and sold at this office.

KUSTEL'S CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver ores generally, with 120 Lithographic Diagrams, 1867. The most complete treatise. Published at this office. Price, \$5. Postage, 50 cts. extra.

Any person receiving this paper after giving an order to stop it, may know that the order has failed to reach us, or that the paper is continued inadvertently, and they are earnestly requested to send written notice direct to us. We aim to stop the paper promptly when it is ordered discontinued.

Dewey & Co. { 224 } Patent Agt's.

DIVIDEND NOTICE.

The German Savings and Loan Society.

For the half year ending December 31st, 1876, the Board of Directors of the German Savings and Loan Society has declared the dividend on Term Deposits at the rate of Nine (9) per cent. per annum, and on Ordinary Deposits at the rate of Seven and One-Half (7 1/2) per cent. per annum, free from Federal taxes, and payable on and after the 15th day of January, 1877. By order, GEO. LETTE, Secy.

DIVIDEND NOTICE.

San Francisco Savings Union, 532 California St., cor. Webb.

For the half year ending with December 31st, 1876, a dividend has been declared at the rate of Nine (9) per cent. per annum on Term Deposits, and Seven and One-Half (7 1/2) per cent. on Ordinary Deposits, free of Federal tax, payable on and after 15th January, 1877. LOVELL WHITE, Cashier.

Mining and Other Companies.

Aetna Tunnel Company.—Location of principal place of business, San Francisco, California. Location of works, Alta City, Salt Lake County, Territory of Utah.

Notice is hereby given that at a meeting of the Board of Directors, held on the second day of January, A. D. 1877, an assessment (No. 1) of three cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary, at the office of the company, Room 6, No. 420 California Street, San Francisco, Cal. Any stock upon which the assessment shall remain unpaid on Monday, the 25th day of February, 1877, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 19th day of March, 1877, to pay the delinquent assessment, together with costs of advertising and expenses of sale. JAMES M. HAYEN, Secretary.

Office, Room 6, No. 420 California Street, San Francisco, California.

Great Blue Gravel Range Mining Company.—Location of principal place of business, San Francisco, State of California. Location of works, Placer County, State of California.

Notice is hereby given that at a meeting of the Directors, held on the 22nd day of December, 1876, an assessment (No. 7) of Fifty Cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin to the Secretary, at the office of the company, Room 33 Merchants' Exchange, San Francisco, Cal. Any stock upon which this assessment shall remain unpaid on Monday, the 25th day of January, 1877, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Wednesday, the 14th day of February, 1877, to pay the delinquent assessment, together with the costs of advertising and expenses of sale. W. BRYANT, Secretary.

Office, Room 33, Merchants' Exchange, California street, San Francisco, Cal.

Howland Tunnel Company.—Location of principal place of business, San Francisco, California. Location of works, Alta City, Salt Lake County, Territory of Utah.

Notice is hereby given, that at a meeting of the Board of Directors, held on the second day of January, A. D. 1877, an assessment (No. 1) of three cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary, at the office of the company, Room 6, No. 420 California Street, San Francisco, Cal. Any stock upon which the assessment shall remain unpaid on Monday, the 25th day of February, 1877, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 19th day of March, 1877, to pay the delinquent assessment, together with costs of advertising and expenses of sale. JAMES M. HAYEN, Secretary.

Office, Room 6, No. 420 California Street, San Francisco, California.

Josephine Gravel Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Brushy Canyon, Placer County, California.

Notice.—There are delinquent upon the following described stock, on account of assessment (No. 2), levied on the 6th day of December, 1876, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Amount.
Boyd, Jno F, Trustee	10	1500	150 00

PATENTED

CAST STEEL SHOES AND DIES.

Guaranteed Cheaper than the Best Iron. IMPORTANT NOTICE.

Reduction in Price from 16 Cents to 12 Cents Per Pound.

Owing to our largely increased business, the present low price of iron from which our Steel is manufactured, and the improved facilities for casting and forging, we take great pleasure in announcing that from and after this date we will supply our IMPROVED CAST AND FORGED STEEL SHOES AND DIES FOR QUARTZ MILLS at twelve cents per pound, delivered at San Francisco or Sacramento, instead of sixteen cents, as heretofore.

We also furnish Steel Plates for Blake and other Ore Crushers, Steel Gut Gearing, etc., for Mills and Hoisting Works, Steel Pan Shoes, Battery Cams and Tappets, etc., etc.

N. B. - Also manufacturer of Hooker's Deep Well and Double-Acting Force Pump. Received the Silver Medal awarded at the last Mechanics' Fair in San Francisco.

\$1,000 Challenge Ore Feeder,

AWARDED FIRST PREMIUM

At the Tenth Industrial Fair of the Mechanics' Institute.

It may be considered as now fully demonstrated, by careful and long-continued experimentation, that the plan upon which a perfect ore feeder must be constructed is that of the carrier, and not that of the shaking table. Uniform and accurate feeding is not possible upon the latter plan. The ore must be evenly carried, upon a steadily advancing plane or table, to the line of discharge, and there simply dropped. Spasmodic or jerky contrivances will not answer the purpose.

REFERENCES.

A letter received from the Julian Mill, Newcastle, says of the Carrier Feeder: "It is the most perfect Feeder we have ever seen; don't see how any mill can do without them." - A letter from Mr. C. C. Belding, of Amador County, speaks in the highest terms of them. - Two of the machines were shipped to the Bunker Hill Mill, also Gover Mill, Amador County. - Mr. Stevenson, of Boston Mill, Gold Hill, Nevada, says they are the best Feeder he has ever seen. - Soulsby Mill, Tuolumne County. - California Company, Nevada City. - Omaha Gold Mining Company, Grass Valley. - St. Patrick Mill, Placer County.

\$1,000 CHALLENGE.

Backward in Coming Forward.

C. P. Stanford Fails to Come to Time on the Challenge of \$1,000 to Test the Merits of His Ore Feeder as Against Mine. The Challenge is Still Open to Him or any one else. GENTLEMEN, Put up or Shut up.

A letter has been received from the Crescent mine, Plumas County, in which it states that the Tulloch is a failure as against the \$1,000 Challenge Feeder of Hendy's.

We warrant the machines to give perfect satisfaction, and to be a better and more durable Feeder than any other in the market, and will sell them as cheap as any other of its class.

IN SHORT, THEY ARE THE MOST

ECONOMICAL, SIMPLE, SAFEST & DURABLE
Engine in the World

We Fully Guarantee Them in all the Above Particulars.

They are Manufactured by the

Colt's Patent Fire Arms Manufacturing Co.,

Who have spared no expense in getting up special Tools and Machinery with which to build these Engines, so that

Every Part is Made up to a STANDARD GAUGE,

And are perfectly interchangeable, the importance of which will be understood by all who are at all familiar with machinery. Thus, every engine of a given size is an exact duplicate of every other one of that size, and in case of breakage, the broken part can be immediately replaced by its perfect duplicate. The inventor of this Engine had in view, in its construction, the great need that exists for a perfect Steam Engine—of small power—adapted to all kinds of light mechanical work, and that should also combine all that is good in Steam Engines. The first point was to secure a perfectly philosophical boiler and furnace, in order to insure the most perfect combustion, and to take up the greatest amount of heat in generating steam. The second point was to make a perfect cut-off Engine, working steam expansively, and keeping up the temperature of the cylinder to prevent loss by radiation or condensation. The third point was to combine and make the whole a mechanically and scientifically correct machine. The result is

The Greatest Amount of Power Proportioned to the Amount of Fuel Consumed,

This proving the fact—well known to men of science, THAT WATER IS THE BEST MEDIUM to transmit the mechanical forces generated in the combustion of fuel, to the production of motive power.

Double and Single Portable Saw Mills.

These Mills are built in the strongest, most durable and workmanlike manner, and are capable of driving any size saw up to 64 inches. They are furnished

With Improved Friction Feed and Gig Back,

Both being operated by the same lever; no belt being used to gig back. They are capable of

Cutting From 8,000 to 12,000 Feet Per Day.

Every Engine is Fired up and Tested before it leaves the Factory.

"BOOKWALTER" ENGINE.

AMES' CELEBRATED PORTABLE ENGINES.

These Engines are manufactured by the same firm (Ames Iron Works) that make the Ames Strawburners; the same care is taken, and the same extra quality of material, first-class workmanship and finish is used in their manufacture as in the Strawburners. The Engines are made fully as well and in better style than most stationary engines are, and intended for use as such when desired. There are comparatively few cases, however, where they cannot be used in their portable shape as such. They are certainly more cheaply and quickly set and put in operation; occupy less space; have all the steam, exhaust and water connections fitted and complete. They require no skilled machinists and masons to set them up in running order. The "Ames" are carefully tested and run with steam at the shop and made perfect there, which cannot be done with the ordinary stationary engine. We claim that the Boilers, Steam and Exhaust passages, and other vital points of these Engines are scientifically proportioned in accordance with the best experience and use of the Steam Engine Indicator; also, that as the manufacturers make a specialty of Portable Engines and Strawburners, we sell a better and larger engine for less money than those who do not confine themselves to the manufacture of any "particular" article. We will not attempt in this space to enumerate the uses to which the Ames Engines have been applied, but merely make the assertion that no style of engine in the United States can surpass them in economical adaptability to "any" work or location. The larger sizes, from 15 to 40-horse power, have met with great success, on account of their large boiler capacity, in driving saw mills, and other uses where slabs, saw dust and other light fuel is necessarily used. A saw mill and corn mill, or any two machines, can be driven at once direct, without the intervention of shafting and pulleys. They are mounted complete, with all connections, and fully tested with "steam" and hydraulic pressure before shipment—until they are known to be complete and perfect in all their parts. They are furnished with Smoke Pipe, Governor, Heater, Pump, Steam Gauge, Water Gauge, Whistle, Safety Valve, Gauge Cocks, and Oil Cups.

Mechanical Ore Concentration and Separation—No. 18.

(Written for the Press by FRANCIS M. F. CAZIN, M. E.,
Santa Fe, New Mexico.)

Assorting According to Size.

When speaking of the principles on which mineral dressing is based, it has been stated that certain action of mineral particles tending to separate them locally by difference in speed or tendency to move can only be depended upon when particles of equal (or at least very similar) size are made to act together. This being a fact established by experience as well as by theory, it would, indeed, have no practical purpose whatever to ventilate what similar action particles will exercise although of differing specific gravity when also of different size, size and gravity neutralizing reciprocally. This is all very useful for the studious engineer, to assist him in avoiding blunders, as they are made by the thousand by the uninitiated, but here, where I do not intend but to write for a direct practical purpose and not to discuss or to indulge in scientific intolerant slang, it is sufficient to say, **Without Sizing No Fully Successful Mineral Dressing.**

To deny this in theory as well as practically is proving incompetence and making a fool of oneself, as well as trifling with the means that may be miscarried in fruitless attempts.

When speaking about the "breaking" of the ore, it has been explained that the nature and quality of the ore has in every special case to be consulted, in order to determine in how large a size the ore should be broken, for separating the rock successfully from the valuable parts.

Now it is impossible to break rock by power, into any size, on an average, without at the same time breaking part of it into somewhat smaller sizes. It will consequently be required, in all cases, to work more than one size in the separating machinery. It has also been explained before, that in breaking by crusher and rollers, such sizes coming from the crusher small enough not to require further rolling, should be kept out by screen sizers (as is done in Dodge's combined crusher and rollers); and also, that the material is most advantageously treated dry until ready for the separation and preliminary sizing thereof.

It therefore remains to indicate the most favorable shape of dry as well as wet screens (sizers). There is no mechanic who will not admit at once that the inclined cylindrical form, where the motion has to be imparted to an inclined shaft and the entire weight pressed toward one friction is disadvantageous when compared with the conical form, where the central shaft is horizontal. Nevertheless a St. Louis journal, professing to be competent in such matters, puffs up the product of a St. Louis foundry, and recommends the inclined cylindrical shape. This is only one of the many cases where incompetency is taking the middle of the track.

The capacity of the screens has to be determined according to the quantity the crusher and rollers are able to work, which quantity depends a good deal on the nature of the rock, and therefore cannot be indicated in general.

The figures A and B, in the accompanying cuts, show a screen of middle size, and of such arrangement as by practice proves the most effective. The work and machinery thus far described forms generally the dry department. From this department all the mineral rock passes into the next department, in a state crushed and rolled down to no bigger size than that determined on as the biggest to be used for ultimate separation. The whole bulk is dry, or at least contains no more water than the small quantity clinging to it from the mines, or from atmospheric influences. The entire bulk enters the second department by being dropped into a gutter with a stream of water sufficient to carry it to its destination.

The Rain.

The good substantial rainfall of the past week has entirely dissipated the almost universal fears of a dry season. The farmers wear smiling faces in prospect of an abundant harvest, and the city people, who are indirectly interested, are happy to see the rain. The miners, who have needed the rain as much as the farmers, are joyful over the good prospects of a plentiful water season.

The fine, pleasant weather of the past two months has been unfavorable for gravel mining in one sense, but it has been good for quartz miners. There has been but little more water to be pumped out from that class of mines, than there usually is in summer, and those engaged in prospecting or opening up new ledges, have had but little to contend with from the elements.

Up to within a short time since there was water enough for the gravel miners, but for several weeks our many claims have been waiting for water. The opportunity has been taken, however, to put the claims in first-class order for winter, and we do not doubt but that it has been better for the miners to be so well prepared. The storm of this week has extended all

REVOLVING DRY SCREEN.

over the State and promises an abundant supply of water and snow. It indicates, moreover, that more will come, and the miners now need have no further fear of a dry winter. After all the time the miners have had for preparation they ought to make a good showing next year, and we think they will.

ACADEMY OF SCIENCES.—The regular meeting of the Academy of Sciences was held on Monday evening last. William B. Hyde was nominated for life membership. Mr. Lockington read a paper on various specimens of crustacea of the Pacific coast. Mr. Edwards presented a paper, in continuation of his series on the *Lepidoptera* of the Pacific coast, describing a new and beautiful species of moth, from Kern county, making the fourteenth species now found. He remarked that specimens of these are so rare that it would be hopeless for foreign collectors to enrich their museums from this source. Dr. Kellogg read a paper on three new plants. Mr. Edwards acknowledged with thanks the compliment paid him at the last meeting, of electing him a life member. Professor Davidson read a paper on the irrigation of Egypt.

BULLION SHIPMENTS.—Since our last issue shipments from the prominent mines have been as follows: Modoc, January 11th, \$6,620—total to date, \$60,257; California, 12th, \$191,875.73—total for January, \$1,288,211.06; Con. Virginia, 13th, \$66,565.32—total to date, \$125,389.19; Chollar, 13th, \$7,070.02; Ophir, 12th, \$3,394.84; Tybo Con., 9th, \$5,873.86—total to date, \$14,686.16; Leopard, 9th, three bars bullion, value, \$4,923; Manhattan, 16th, \$12,800; Modoc, 13th, \$5,630—total to date, \$65,887; Tybo Con., 13th, \$10,893.78—total to date, \$25,579.94; Northern Belle, 14th, \$15,207.28; California, 17th, \$107,771.32—total to date, \$133,895.91; Con. Virginia, 16th, \$38,563.80—total to date, \$163,952.99; Modoc, 15th, \$5,680—total to date, \$71,567.

EUREKA VS. RICHMOND.—A dispatch from Eureka, Nevada, gives the following particulars of a suit to determine the boundaries of two mines: One of the most important mining suits ever tried in Eastern Nevada is now on trial in the District Court, the Eureka Consolidated company being plaintiff and the Richmond company defendant. The former brings action at law for the recovery of \$2,250,000, estimated value of 35,000 tons of ore at \$70 per ton, which is alleged in the complaint to have been taken by defendant from plaintiff's ground. Plaintiff also will file a bill in equity, asking for an injunction restraining defendant from further working the disputed ground until a trial of the case can be had. The famous Potts chamber, from which so large an amount of rich ore has been extracted by the Richmond company, is situated in the disputed ground. Plaintiff, in its complaint, bases its claims to the ground under an act of Congress, and also under the covenant of compromise entered into between the two companies, in the settlement of the celebrated suit between them which was tried in the District Court several years ago, and which resulted in the disagreement of the jury. The injunction matter will probably come be-

The California Bonanza.

The annual meeting of the California mining company was held on Wednesday of this week, when the reports of the officers were presented. The Superintendent gives a detailed report of the condition of the mine underground, which we have not space to publish in this issue. In the first part of his report he says: "The California mine has yielded during the year ending December 31st, 1876, 128,800 15-20 tons of ore. Of this ore 127,540 12-20 tons have been reduced, leaving on hand in the ore houses and at mills, 1,260 3-20 tons, valued by assay at \$189,000. The ore reduced has yielded bullion of the value of \$13,400,841.40, being 73% of the assay value of the ore. The value of the gold in this bullion was \$6,488,640.58, and of the silver, \$6,912,200.82. The average yield of the ore per ton is \$105.07.

The exactions to which the bullion produced has been subjected—in the way of heavy discount on silver, local taxes on net proceeds—and the cost of transportation of the bullion, have materially reduced the apparent yield.

The President's report is as follows: The payment of monthly dividends of two dollars per share (\$1,080,000) commenced on the 15th of May last; and, while the stockholders have been kept in constant alarm by sensational rumors, given greater publicity by journals purporting to furnish reliable information, the mine has continued to produce the necessary amount of bullion for the payment of these dividends. The year has been singularly uneventful in misfortune; during that period the extraction of ore has continued with scarcely the interruption of a single day, or the necessity of recording any accident. The management which has achieved so happy a result is entitled to your confidence and approval.

The heavy discount on silver has materially affected the profits of the production; and this would have been even more sensibly felt had not the percentage of gold been unusually large. The recent advance in silver promises an improvement in this respect for the coming year.

The following figures show to what importance the mining business has grown, and how extensively your stock figures in it. There have been transferred during the year 850,000 shares. As every transfer indicates a transaction, by placing the average price for the year at 60, we find that \$51,000,000 represents the aggregate of these transactions.

The Secretary reports the gross product of the mine at \$13,400,841.50. Total disbursements, \$13,742,200.22, including \$8,640,000 paid in dividends. The present overdraft is \$339,637. The reduction of ore cost \$1,613,472.70; discount on bullion, \$895,521; salaries and wages, \$412,509; supplies for mine, \$296,887; C. & C. joint shaft, \$191,908; bullion freight, \$93,066; hoisting ore, \$70,915; assaying, \$34,804; interest and exchange, \$53,715; taxes, \$15,175; bullion in hands of Bank of Nevada, \$1,342,967.

There are supplies in the mine valued at \$36,750, and machinery worth \$48,257.

SUPERINTENDENT UTQUHART, of the Fire Alarm Telegraph, wants to make arrangements by which alarms of fire may be heard in districts where the sound of the alarm bells is not audible. He proposes to place gongs in several of the large foundries and factories, which shall be connected with the wires of the alarm telegraph, and when an alarm is struck on these gongs, to have the same repeated by the steam whistles in these places.

A BILL has been introduced in the Nevada Legislature by Baker, compelling foreign corporations to reincorporate in that State and have offices there.

fore the court some time next week, but the case cannot come to trial before next March.

MINING SUIT.—A dispatch from Salt Lake says: About two weeks ago the English stockholders of the Flagstaff mine sent A. G. Hunter to take charge of their property, it having been under the management, for several years past, of J. N. H. Patrick. Upon his arrival here Mr. Hunter obtained possession of the mine through an attachment of the Justice's Court at Alta, since which time there has been a contest for possession before Judge Shaeffer, of the Third District Court, which was decided to-day in favor of the English party. This has been the most productive mine in Utah for the past five years.

OUR REVIEW.—Owing to the use of so much space for our annual mining review this week we have omitted our usual illustration on the ninth page. We have also left out other matter of which want of room prevented the insertion. Our review will be found very comprehensive in character, and is well worth perusal by all interested in mining development, as it gives facts and figures from all localities on the coast. The statistics given will be found reliable, and may be taken as a basis for calculation.

THERE is a probability that Dakota will be divided and a new Territory erected out of a portion of her lands, to be styled "Huron." A bill to that effect has already passed the Senate. The proposed new Territory is to be formed from the northern half of Dakota, and will comprise 70,000 square miles, with a population of about 10,000. The soil is said to rank equal for productiveness with the best in the United States under corresponding temperatures.

Rights of Stockholders.

Discussion at the Consolidated Virginia Meeting.

The annual meeting of the Consolidated Virginia mining company was held last week, and in our last issue we gave in full the official reports. Want of space, however, prevented the publication of any of the proceedings of the meeting, which were pretty exciting. Some of the stockholders contended that the management had not acted fairly, while others thought they had. We append that part of the proceedings of interest to the general public.

After the report of the Superintendent was read Mr. S. P. Dewey rose and said; I second the motion to receive the report, and take the occasion to congratulate the shareholders on the favorable condition of the mine and the prospects—now a certainty—of an early resumption of dividends and their continuance for a long period of time, certainly until the 1600 and 1700-foot levels are exhausted of the rich bodies of ore known to extend to that depth. Of the

Truthfulness of this Report

I have not a doubt, as the statements of the Superintendent are confirmed from other reliable sources. My only regrets are, first, that these facts were not given to the public a month ago, strengthening the stock and preventing the terrible sacrifices so many of the shareholders have been made to suffer; and, second, that the report does not embrace the workings of the diamond drill, about which so much anxiety is felt by the shareholders, who feel that its operations and disclosures are reserved to the benefit of the managers alone. We are entering upon a new year, and I trust a new era in the management of the company's affairs. What we want most is information—all the information that exists from day to day regarding the developments of the mine. This, stockholders have a right to demand, and this alone will give all an equal chance, and preserve them from becoming the prey and victims of designing manipulators. At the proper moment in the proceedings of this meeting I propose to offer a resolution or two on this subject of information, which I trust will receive your support and approbation.

The Diamond Drill.

Mr. Mackey here said that so far as the diamond drill went, there had not been a diamond drill run in the mine below the 1500-foot level, and therefore Mr. Fair could not have reported anything respecting it. As for the managers keeping back information, he had not done so, and he did not believe that Mr. Flood had. All the information to be obtained about the mine was included in the Superintendent's weekly reports, and they were open to the public. He repeated his denial of the use of the diamond drill below a certain level.

Mr. Dewey said the managers had not denied it over their own signatures. If they had done so the people would have believed them.

After an angry discussion between Mr. Dewey and Mr. Flood, Mr. Mackey said: Come, come, gentlemen. If Mr. Dewey will gamble in stocks he must expect to lose once in a while, and at any rate this is no time to bring up personal matters. I want to say now—and not only for the benefit of Mr. Dewey, but all the gentlemen here present—I am the largest individual stockholder in the company, and have more at stake than any man in it. I work the mine with Mr. Fair in Virginia, and it is simply impossible for us to tell two or three days or a week ahead what the mine may develop. We cannot promise anything for the future to a certainty. Events are constantly happening to upset our calculations. Hard rock, caves, bad air and a hundred things occur at any moment to retard our progress. The management have done as well as they can and can do no more.

Mr. White—who, it may be here stated, represented Brighton in the English Parliament for 16 years, and who purchased \$200,000 worth of California and Consolidated Virginia stock when in the 80's—here came to the front. He said that he appeared in his own behalf and in behalf of numerous English stockholders who were dissatisfied with the course of the bonanza managers. They had kept their affairs too secret, a method of transacting business quite inconsistent with British frankness.

To this Mr. Mackey warmly replied that an Englishman could know nothing about the working of an American mine, a matter regarding which even himself and Mr. Fair might be mistaken. Those who were so much given to blowing about the mine ought to come to Virginia and try to run it themselves. The statement had been made that they had been using a diamond drill in prospecting the lower levels; the fact was that they had not used a diamond drill at all below the 1550-foot level.

Mr. Dewey—I merely asked for information. If that is a fact I withdraw my statement respecting it.

Solomon Heydenfeldt replied generally to Mr. Dewey's remarks.

Regular Statements Wanted.

Mr. Dewey reiterated what he had said about the desirability of regular statements by the managers. He also recalled the remark made by Mr. Flood, in an interview made some months ago, to the effect that the prospects of the Consolidated Virginia mine were excellent, and that it would continue to pay dividends uninterruptedly for a long time to come. Mackey

interrupted by asking if it was not Tom Fitch who said that, and continued: "The statements to which the gentleman alludes have been published regularly for the past two years.

Mr. Dewey—I have found these statements true with few exceptions. If we had the same means of obtaining information here it would be a good thing.

Mr. Mackey (impetuously)—Now, Mr. Dewey, my dear sir, if you will come up to Virginia you shall have all the information you can possibly get.

Mr. Dewey—What I desire to ask on my own behalf, and in behalf of other stockholders, is that the management do something to give us more confidence.

Mr. Mackey—I suppose Mr. Dewey is dissatisfied in regard to the depreciation of his stock as well as in respect to alleged mismanagement.

Mr. Mackey—Silver is high and discount is high. The expenses of running a mine are enormous. The wages of the men from top to bottom are \$4.50 per day. A mill cannot be put up for less than \$500,000.

Mr. Dewey—We know all that.

Mr. Mackey—Not a man can be hired to work in the mines for less than from \$4.50 to \$10 per day. The expenses of handling the ore and keeping the mines in order are very heavy. Then there are great obstacles to be overcome, such as water, ventilation, danger of fires, etc. Then if there is any delay people say there is something wrong, and get mad. What are you going to do about it?

Mr. Dewey re-read his remarks on the superintendent's report, and renewed his motion to adopt, which was put and carried without a dissenting voice.

In voting for trustees 483,136 shares were voted for the regular Flood & O'Brien ticket and 32,335 for the opposition.

A Resolution.

Mr. Dewey read the following:

Resolved, That the directors be instructed to make or cause to be made and published monthly statements of the financial condition of the mine, showing its receipts and expenses with the balance to debit or credit at the end of the fiscal month.

Mr. Murphy—That has never been done by any mining company in San Francisco before, so far as I know.

Mr. Dewey—Not a man can be hired to work in the mines for less than from \$4.50 to \$10 per day. The expenses of handling the ore and keeping the mines in order are very heavy. Then there are great obstacles to be overcome, such as water, ventilation, danger of fires, etc. Then if there is any delay people say there is something wrong, and get mad. What are you going to do about it?

Mr. Heydenfeldt—There is a difficulty in the way of this. The fiscal condition of the company can hardly ever be told at the end of the fiscal month. It often happens that just at that time the products of the mine have not been fully realized, because large amounts of bullion may not have been sold. It has sometimes occurred in past year, that there has been a great decline in stocks. At one time this decline reached 27% and the management wisely declined to sell their bullion at such an enormous discount, holding over very large amounts for improved rates, that they might advance the interests of the company. They did not, on this account, cease the payment of dividends, but overdraw the company's account at the bank to pay those dividends, rather than that the stockholders should suffer. Statements made at the end of the month might often give a very inadequate idea of the financial condition of the company. They might have a million dollars in bullion on hand, and might have more than a million overdrafts. All that the trustees can be required to do is to give the financial condition of the company as nearly as possible.

After some discussion Mr. Dewey offered the following:

Resolved, That the trustees be and they are hereby authorized and instructed to procure and deposit with the secretary, full, true and correct copies of all existing and future surveys, plans and drawings of the underground workings of the mine, and to keep the secretary fully informed as to the condition and profit of the mine, and that they direct him to exhibit such plans and drawings and surveys, and to impart all official information to any stockholder during business hours when requested so to do.

This resolution was at first presented in more extended form, but abbreviated to this shape.

Mr. Dewey went on to say that in all the mines with which he had ever been connected as director or chief officer, they had always had plans and drawings showing the working of the mines, corrected from day to day, illustrating the sinking of winzes, the running of drifts, etc. These enabled the stockholders to watch the progress and development of the mines, and correct all misrepresentations likely to do them injury. He continued his remarks as follows:

The object of the resolution is to establish a bureau for information where every stockholder shall be at liberty to go for official information concerning the condition and prospects of the mine. Private or personal statements made by individuals, whether in the management or out, do not suffice; on the contrary, they are detrimental to the general mass of stockholders. A few importunate or favored ones may be benefited, while the many who are equally entitled to information learn but little of the affairs of

what may possibly affect their entire fortunes. Added to which, the system of imparting private and individual information leads to misrepresentation and suppression of truth by the party especially favored. What one has a right to know is equally the right of all, and no statement can have such weight with the shareholders as that which is official. Who does not know that the want of official information respecting the mine and its prospects has within the past 90 days depreciated the value of the stock of this company many millions of dollars, and caused the ruin of hundreds? Who does not believe that this ruin would have been averted by an official statement that the stoppage of dividends was the result of temporary causes only, and not from impoverishment of the ore body, as was publicly and continuously asserted by persons interested in depreciating the shares for stock jobbing purposes? Had the secretary, under authority such as is embodied in this resolution, exhibited to the shareholders full plans of the mine and published candid statements of its condition and of the finances of the company, announcing the fact, which is doubtless undeniable, that so soon as the necessary connections in the mine could be made, involving a period of probably from 30 to 60 days,

Dividends would be Resumed,

Under favorable conditions for their continuance over a long period of time, confidence in the mine and its management would have gathered new strength instead of weakening, the broker and capitalist would not have pursued the marginal customer, the panic we have witnessed would have been averted, and many a man and woman now impoverished by reason of his or her investment in the bonanzas would be yet happy and hopeful of the future and patient in the present. Considering, too, the fact that it is but a few months since the chief among the trustees of the company, and he who is credited by the public with being the head and front of its affairs, gave publication through the press of this city to these words: "I tell you, sir, that these mines will pay dividends right straight along, and will continue paying them when those who are maligning them are cold in death," etc. He certainly owed it to himself, if not to his fellow-shareholders, and especially those who had invested upon the truthfulness of such statements, that some explanation should be given of the causes which produced so serious a falsification of his prophecy. I have great faith in the future of the bonanza mines, and believe that the best portion of their great wealth is yet to be realized. This faith cometh from knowledge not obtainable from official sources or through the channels of this office, as it should be. Give us faithfully the information called for by our resolution, with an honest administration of affairs at the mine, and I venture the prediction that the value of our shares will enhance as rapidly as they have depreciated under the dark-lantern policy.

The Directors' Views.

Judge Heydenfeldt—I am satisfied that the substance of the requisition is not in the power of the stockholders at all. The management is instructed in the nature of its duties by law. They have been duly elected to bear the burdens of office. Even if they were disposed to give way to the fancies of stockholders, they are not sufficiently well informed to have definite views in regard to what they want.

Mr. Dewey—We merely want information in regard to the mines.

Judge Heydenfeldt—You must appeal to the trustees, then, to make an order of that kind.

Mr. Dewey—The resolution is an instruction which we give the trustees. To say that the power does not rest with the stockholders still, merely because they have elected trustees, is an absurdity.

Mr. Dewey went on to say that every stockholder had a right from day to day to know what his paid agents were doing, and the idea that any man, or any set of men, had the right to refuse such information, was an absurdity. A man with 100 shares of stock had just as good right to know about the affairs of the company as the man who owned 100,000. He risked his property equally—perhaps ran even greater risks, as what he had invested might be all of his little fortune. To ignore the demand of these people was doing them a great injury.

Mr. Mackey—It is very hard to reply under the circumstances. I just want to make a few remarks in regard to the honesty of the management. I defy any gentleman to say that there has been any dishonesty in the management of the Consolidated Virginia mine.

The resolution was finally adopted, Mr. Heydenfeldt voting against it.

The Nevada Mill Company.

Mr. Dewey—I have another resolution that seems more important than any yet offered. I have considered it of sufficient importance to give it a preamble. It is as follows:

WHEREAS, The Nevada mill company, which was organized and consists of Messrs. Flood, O'Brien, Mackey and Fair, have within the past year erected a large and efficient mill for the reduction of ores, and have used said mill solely for reducing the ores of the Consolidated Virginia mine at a profit to said mill of about \$600,000 per annum, besides tailings, and at a corresponding loss to the stockholders of the company,

Resolved, That the trustees be authorized and instructed to enter into negotiations with some mill company for the purchase of said mill at any reasonable price, and that in the event of a failure to effect such purchase, they be instructed

to purchase any other desirable mill property or to cause to be constructed without delay one or more mills adequate to the necessities of this company.

Rev. Mr. Briar came suddenly to his feet after the reading of this resolution. He said that, in his opinion, the less property a company had the better they were off. He might sell out his stock in the mine, and retire from business, when he would find himself a mill-owner contrary to his will. He had rather Flood and O'Brien, Mackey and Fair, would run their mill up there independent of the mine, and they would run the stock-mill down here.

Mr. Dewey—The importance of this resolution to the welfare of the company can hardly be exaggerated. Indeed, I may say that its future success depends in a great measure upon its adoption. With this conviction and knowing to what extent the interests of the company—through the inconsiderateness of stockholders in disposing of their proxies—depend upon the favorable action of the men who are at the same time our trustees and owners of the mills sought to be acquired, I venture an appeal to them to favor this resolution; believing as I do that such an abnegation of personal interests in favor of the company whose interests they represent, will add to their great wealth that which is of still greater value, the good opinion of their fellow-men, and the gratitude of the shareholders who have so generously confided to them their interests and so long and patiently submitted to this injustice. Every one at all conversant with the facts knows to what a fatal extent the mill interest, as it is called, is eating out the vitals of the mining interest on the famous Comstock. Why, sirs, I venture the opinion that but for it the Ophir, the Chollar, the Belcher, would to-day be dividend-paying mines, with a vastly appreciated value in their stock.

Why is it that Ophir, with a bullion product of \$2,350,000 the past year, pays nothing to the shareholders, while its shares have depreciated during the same time from \$75 to \$17, the whole mine, with \$350,000 in its treasury, selling to-day for less than two-thirds of the year's product and but little more than the value of its plant? Why is it that the Chollar has for the past five years been made to yield an average of 100 tons of ore per day, and that of a grade just sufficient to pay its diurnal tribute of \$500 a day to this mill interest and nothing to stockholders, while if the stockholders had owned their own mills they would have saved, during these five years, nearly \$1,000,000, giving a handsome interest on their investment? The Belcher is to-day turning out an average of 200 tons of ore per day, the milling profit on which is over \$1,000 per day, or 33% per annum on the present market value of the stock, and yet the stockholder gets nothing. With Consolidated Virginia the figures assume more stupendous proportions. The company have paid for milling their ores for the past 32 months the enormous sum of \$5,320,000, of which fully one-half is a clear profit and should now be in the company's treasury, saving the necessity for suspending dividends, also the great depreciation in the market value of the stock, and the widespread ruin and distress that have followed. And yet this is not the whole or even the greater part of the losses suffered by these mines through this "mill interest," for, not satisfied with the enormous profits made in the reduction, they claim the tailings also, which of right are and should be the property of the company. The great value of these tailings will be seen by the following figures and estimates: The bullion product of the Consolidated Virginia mine has been in round numbers \$39,000,000; the percentage realized from the mills in reduction averages about 70% of the assay value, which would give the enormous sum of \$16,700,000 to the tailings, of which probably one-half can be recovered by these mill owners. Is it not time then for stockholders to take action against a system that is so fatal to their interests, and by the adoption of this resolution rid themselves at once of this vampire which is sucking out the very life-blood of the mine, and will soon render their stock worthless? Again I appeal to the gentlemen whose duty it is to represent the interests of all the shareholders, to give it their very efficient aid. The great fortunes which they have acquired from mines and mills should now, it seems to me, demand from them this act of justice and a more liberal policy.

Mr. Heydenfeldt—We should vote unanimously in favor of this resolution.

Captain Hall—I must protest against this resolution to purchase the mills. I would not be willing to take my part of the stock and take the chances.

Mr. Wadsworth—I don't want to buy any mills. I think one thing would eat the other up. I believe we can make more money to take the dividends, and let them run the mills.

Mr. Dewey—I have had conversations with the mill men at Virginia on the subject, and have also had an interview with the assessor of the revenue in regard to the milling business. He knows as much as any man how much it costs. He says that the mill pays for itself every 90 days.

Mr. Mackey—That's a mistake, Mr. Dewey.

Mr. Dewey—I have the thing reduced to writing.

Rev. Mr. Briar—I think that the most of those present have perfect confidence in the men who are running these mills. If the proxies authorized to vote here vote to purchase

MECHANICAL PROGRESS.

Notes on D. mills.

Professor Sweet, the mechanic of Cornell University, continues his notes in the *Polytechnic Review*. We quote a few points on drills: The machines for driving drills are as various as can well be imagined, ranging from a bit-stock, turned by hand and forced up by the breast, through a similar device made stronger and turned by one man while the pressure is put on by a lever worked by another; then the fiddle-drill, in which a string passed around a spool and fastened to an elastic bow is used to turn the drill—the ratchet-drill, the crank-drill, the geared crank-drill, the lever-drilling machine, the post-drilling machine, the girder-drilling and boring machine and the radial machine.

With all our modern perfected machinery it seems useless to spend much time in describing such primitive devices as a fiddle-drill and lever-brace, and yet there are times when small holes are to be drilled in large castings, that it costs twice the time and money to move the work to the machine than to drill the hole, providing the workman had the tool and disposition to do it by hand.

In the construction of the fiddle-drill there should be a thread cut on the spool for the cord to work in to keep it from chafing. In the crank-drill for general purposes, the crank direct on the drill-spindle to work without the intervention of gearing is the best, though not so applicable to all positions as one driven with bevel gearing. Where there is gearing it would be an improvement if they were readily changeable to change the speed.

Of the score of ratchet-braces, that is, the devices for working a drill by moving a lever back and forth, there are but few that seem to possess all the requirements desirable. If the ratchet teeth are coarse, there is too much lost motion; if the teeth are fine they wear out, break off, or the pawl soon gets so it will slip over. To overcome these objections the differential ratchet was invented, or rather patented, as no doubt it had been invented a dozen times before. This device consists in placing say three pawls equidistant around a ratchet with seven teeth. Only one of these pawls can engage at once; so while the teeth in the ratchet are strong, there being but seven, the ratchet cannot under any circumstances be turned backwards more than the 21st part of a circle before one or the other of the pawls will catch. This overcomes both of these difficulties, but leads to another, viz., complication, or at least a multiplication of parts. There have been a half dozen or more friction devices invented for the same purpose—the object sought being to produce a tool that there should be no lost motion whatever, and also one that would work silently. The noise of the ratchet is thought by some to be objectionable, but none of the devices have proved anything like a success. The most of the friction devices which work at all have more or less lost motion—none of them are durable. The greater part of them fail to work in all positions, and as to doing away with the noise, it could be done easily with an ordinary pawl if it were worth doing. The drill is forced up to the work by the screw at the back being rested against some temporary structure, or support. It is better to have this support elastic or yielding than rigid, for with a rigid support the screw must be set out at every revolution of the drill; whereas, if it is yielding, the drill may be revolved several times and the spring will keep to its cut. A chuck fitted to the ratchet-brace, so as to use the ordinary drills of the shop instead of having to have an extra set for that special tool, is economy.

A drill will stand to take a heavier cut when used by a ratchet-brace than it would be either possible or policy to use when run by the drilling machine; the slow speed at which it is run does not generate heat enough to endanger the temper.

NEW GERMAN PATENT LAW.—The *American Manufacturer* says: The German patent law has long been a source of complaint on the part of inventors, and the aptitude of German manufacturers for appropriating to their use the creation of others' brains has become notorious. We are glad to learn, however, from our foreign exchanges, that a bill has been introduced into the Reichstag which promises a great improvement in the patent law of that country. The new bill provides that patents may be granted for a term of 15 years. For every patent thirty marks (\$7.14) are to be paid as soon as it is granted, but poor inventors are allowed a delay not exceeding two years. At the beginning of the second year fifty marks must be paid, and fifty marks more every succeeding year. Any person having used an invention before it was patented, may continue to use it without making any payment to the patentee. The latter is, however, bound to permit its use to any one that will pay for it. If this should be refused the patent privileges are lost. The patent office is to have the right of publishing all descriptions and drawings in print, and any person may search the specifications, drawings and other documents in the office.

Encouragement for Intelligent Mechanics.

The Company of Needle-makers, says *Ryland's*, having determined to offer prizes by way of encouraging and developing the art of needle-making in the neighborhood of Redditch, in which locality this manufacture has been established for many years past, the court of the company appointed a special committee to arrange a scheme for that purpose. A committee of manufacturers was selected from the manufacturing district, and the various details of the prize scheme were considered by it. The scheme of prizes sought to develop the art of needle-making under three heads, for which prizes were offered: First, to encourage the introduction of labor-saving machines; secondly, to reward skill in handicraft, and lastly, to stimulate the inventive and reflective talent of the needle-making locality in the neighborhood of Redditch, by means of prizes for essays in connection with the needle manufacture. With reference to labor-saving machines, none were submitted for competition; the conditions stated that they must have been originated since the first of January, 1875, and although a great deal of machinery has of late years been introduced with success into the manufacture, only one machine is known that would come within that stringent condition, and that was not entered. In the section, "Improvement in any of the processes of sewing-needle manufacture," four inventions were sent in. The judges awarded the first prize to Benjamin Hill, needle hardener, of Studley, for a pair of foot shears; and a second prize, consisting of £1, from local sources, with a certificate of merit, to Richard Bennett, junior foreman, of Redditch, for a "double polishing buff." Section No. 3, prizes for handicraft (tool making), produced, as might have been expected, the greatest number of competitors and the keenest competition. The prizes in this section were offered for the best specimens of tool and work for sewing needles and sewing-machine needles. In this section the judges awarded the principal prize to Chas. Townsend, tool maker, Redditch. For sewing machine needle tools the judges awarded the first prize to Jonah Warner, Redditch. The prize for the best essay was not awarded; a second prize for an essay was given to W. Shrimpton.

We are decidedly of the opinion, says the *Iron Age*, that a like effort to encourage progress in any of the leading manufacturing industries of the United States would be attended with great benefit. The intrinsic value of the prizes need not be great, but the honor of winning them would stimulate intelligent mechanics to master manfully the theory of their trades, and give substantial encouragement to inventive talent by securing immediate recognition for anything both novel and useful. The best way to educate the working classes is to encourage them to educate themselves.

A MODEL ENGLISH RAILWAY PARLOR CAR.—The Great Eastern railway is now running a new saloon, which has been built at the company's works, Stratford. This carriage is divided into five compartments, the one at each end being for servants and luggage respectively. The former is very conveniently furnished with green Utrecht velvet seats and backs, hat nets, etc., and has a bell communication with the body of the saloon, which is approached therefrom through an ante-chamber furnished with a morocco lounge and a falling leaf table, making a very convenient divan. This chamber leads through a sliding door into the body of the carriage, which consists of a spacious saloon, trimmed with maroon morocco, and enlivened with the elaborate floral devices and gilt moldings with which the ceiling is adorned. The furniture and fittings are satinwood, and consist of a couch, settee, arm-chairs, and a folding table at which ten persons can be conveniently seated, the floor being covered with a rich Brussels carpet. The remaining compartment (which is at the luggage end of the vehicle, and is entered from the saloon opposite to the sliding door leading to the ante-chamber) is fitted up with every convenience as a lavatory. The floor is tasseled wood, and the walls are covered with flock paper painted two shades of green, the ceiling being relieved with gold molding. The carriage is built of teak, varnished, and is carried on two bogie under-frames, with an arrangement of springs calculated to give the greatest possible ease in traveling, and is reported a perfect success.

NEW NUT.—A new nut is in use by the Boston and Albany railroad. It is a little thicker than the ordinary nut, and across its face are sawed two slots, crossing each other at right angles and cut almost half through the nut. The opposite side of the nut is convex, so that when it is screwed up tightly its corners, being the first to touch the face of the iron behind it, cause the four sections of the nut, separated by the slots in front, to approach the center of the bolt. This grip is tighter as the pressure behind it is greater, and it causes the threads of the nut to engage more deeply with those of the bolt.

BRITISH NAVY.—During the last 20 years the British government has added 573 ships to the navy by building, and has purchased 44 more. It has sold 110, broken up 125, and 31 have been lost. The number of Gatling guns in use is rapidly increasing. The large iron-clads are now all armed with them, and several have been sent to Malta for the Mediterranean fleet.

SCIENTIFIC PROGRESS.

Magnetic Declination.

The latest issued report of the Coast Survey contains a new discussion of "The Secular Change of Magnetic Declination in the United States and other parts of North America," by Charles A. Schott, Assistant, U. S. C. S. Forty-three stations are represented in the discussion, and over 400 observations. Formule are given for each station, with decennial tables computed therefrom. Mr. Schott says:

"A cursory examination of the column containing the epochs of greatest easterly excursion, the deflecting force producing the secular change attaining them an easterly maximum, shows that the needle became stationary in direction, and then reversed its secular motion, in the New England States toward the end of the past century, in the Atlantic coast States to the west and south early in the present, and in Mexico about the first third of the present century. In California, Oregon and Washington Territory, it has not yet reached this condition. We thus have the following epochs for comparison: Halifax, about 1711; Portland, Portsmouth, Newburyport, Salem, Boston, Cambridge, Nantucket and Providence, about 1779; Hartford, New Haven, New York, Hatborough, Philadelphia, Washington and Cape Henry, about 1800; Charleston, Savannah, Key West and Havana, about 1800; New Orleans, about 1831; Vera Cruz, Mexico, Acapulco and San Blas, about 1837; San Diego, Monterey and San Francisco, expected about 1907 (yet very uncertain).

We are thus directed to the extreme north-eastern States for probable indications of what may be expected to follow on the seaboard in more southern and western States. Respecting the secular movement of the needle, apparently a little more than a century passed before the influence which produced the turning of the north end of the needle westward in Maine (increasing there the western declination) was felt in Lower California (diminishing there the eastern declination). In California, Oregon and Washington Territory the eastern declination is at present still increasing, but with a losing rate. By the time the western elongation of the secular change is reached in Maine, we may expect to see the needle in the opposite phase, or at its eastern elongation, in California. We cannot as yet follow this influence directly over the interior of the United States for want of early observations; the westernmost interior stations for which an epoch could be made out were Buffalo, Erie, Cleveland and Detroit; these give the average turning epoch 1794. It may be quite practicable hereafter to trace out curves uniting all stations where the needle was stationary at a given epoch, and again at other epochs for regular intervals of time, say of 10 or 25 years.

GLASS SILK IN THE LABORATORY.—Glass silk, as it is called, is largely used in Germany, and especially in Austria, says the *Journal of Chemistry*, for filtering purposes in laboratories. It is made by winding fine threads of melted glass on rapidly rotating and heated cylinders. Under the microscope the threads appear as fine as the ultimate fibers of silk or cotton; they break more easily than the latter, but are excessively supple. From the inalterability of the substance, it is very well suited for filtering acid or alkaline solutions even concentrated, and various other substances, such as nitrate of silver, albumen, collodion, Fehling's liquor, etc. It affords great rapidity of flow with good filtration. It does not, like filters of paper or tissue, communicate organic matter to the liquids, altering and, perhaps, giving them a disagreeable taste. It is much preferable to amianthus, which, from the arrangement of its parallel fibers, cannot be formed in a flexible ball, and which lets fragments pass that float in the liquid. For analysis it is very advantageous, allowing of a ready determination of insoluble matters deposited; also by calcination and fusion of the glass may be found the volatile principles fixed in passage of the liquid, unaltered with empyreumatic products. The price of glass silk is at present pretty high, but its excessive lightness allows of a considerable number of filtrations being made with a small weight of it. Besides, it may serve an indefinite time if only after each operation it be abundantly washed with water and dried in air.

SPONGY PLATINUM.—The production of spongy platinum, says the *Mettallarbeiter*, is a task more easy in appearance than reality. The principal requirement of spongy platinum is that it should be spongy, but this obvious requirement is very frequently overlooked, and hard and useless masses of platinum are produced through overheating the sponge and running together the finer particles. Into a concentrated solution of muriate of ammonia, drop a similar solution of platinum chloride; a yellow precipitate is formed, which is washed three or four times in hot water to free it from the sal ammoniac. This precipitate, when properly cleaned, and while still moist, is dropped on a very thin platinum wire stretched several times across a small ring of copper, and is then allowed to dry thoroughly. After drying it is slightly heated over a spirit lamp, contact with the flame of which is to be avoided. As above remarked, only very careful heating over the spirit lamp will give satisfactory results.

Important Astronomical Observations.

The *Polytechnic Review* announces that the great refracting telescope, of 26-inch aperture, of the Naval Observatory, Washington, has been diligently employed for some time past in observations of the satellites of the outer planets, Neptune, Uranus and Saturn. A few evenings ago, Professor Hall, at 6 p. m., Washington mean time, observed a brilliant white spot on the central lower portion of the disc of Saturn. On giving notice of this to our chief observatories in the different States, he has had the satisfaction of hearing from several of them that they have since observed the same. He has also watched it closely, for the plain object of determining by these series of observations the true period of the rotation of the planet; an inspection of the text books on astronomy shows a discrepancy in the statement of this period by the Herschels. We anticipate the pleasure of presenting very soon the results of Professor Hall's investigations.

From the report of the superintendent of the Observatory, Admiral Davis, to the Secretary of the Navy, we learn that in connection with the observations which have occupied the great telescope, further interesting discoveries have been made. The companion of Procyon, discovered by Struve, Director of the Imperial Observatory, St. Petersburg, has been diligently searched for without success; but three other close companions of the same beautiful star have been discovered through the lens of the great telescope. These companions have been repeatedly seen at the Observatory, and on their positions being given they have been recognized by American astronomers also at other observatories.

It may interest our readers to learn, in this connection, that a volume prepared at the Observatory for the Centennial is now being distributed to those specially interested in astronomical pursuits, which contains a description of each of the telescopes of the Observatory, accompanied by a heliotype plate of the same; in connection with the several plates of the great refractor, a condensed report is given of its work on the planets, and on several of the larger nebulae. The last heliotype in the volume presents the results of this work in a quadruple picture. The volume is entitled "The Instruments and Publications of the Observatory from 1845 to 1876."

NITROGEN AND ELECTRICITY.—Recent French investigations, says the *Journal of Chemistry*, indicate that atmospheric electricity may have an important influence on the absorption of nitrogen from the air by plants. At a meeting of the Academy of Sciences at Paris in October, a paper was presented by M. Berthelot, describing some experiments he had been making which shed light on this subject. He availed himself of the normal electric tension of the atmosphere. A closed tube of thin glass was placed within another; in the former was a roll of platinum connected with a conductor electrified by the atmosphere, at a height of two meters, or about six feet and a half, while a thin sheet of tin surrounding the outer tube was connected with the earth. The space between the tubes contained either pure nitrogen or atmospheric air, along with moist strips of blotting paper, or a few drops of syrupy solution of dextrose. Twelve of these double tubes were exposed to the air from July 29th to October 5th. In all of them nitrogen was fixed by the organic matter, though in varying quantities. In two cases green spots of microscopic algae were found on the strips of moist paper in tubes containing nitrogen alone, showing a greater fixation of nitrogen in these. The experiments are of much interest as suggesting an influence in vegetation hitherto unsuspected, and we shall await further investigations with no little curiosity.

CURIOUS GEOLOGICAL FORMATION.—Down the Ohio river, at Martin's ferry, was discovered a few days ago, says the *American Manufacturer*, a very curious geological formation about 35 feet under ground. A well was being dug, about one-quarter of a mile back from the river, and at the depth mentioned, under the overlying sand, the workmen found an oval of soft sandstone, in which was embedded a closely-packed mass of hickory-nuts and twigs. Some of the nuts were broken open on the half-shell, while a few were complete even to the outer pods, which were opened at the radial point. There are also some impressions in the stone or hard clay which closely resemble small corrugated mollusks. Readers may form their own conjectures as to the time required for the overlying sand and the earth of the river bank to accumulate, for the nuts and shells would indicate that the locality had once been a part of the shore.

WEATHER WATCHING.—The chief signal officer in his annual report states that during the last fiscal year over 83 per cent. of his "probabilities" of the weather were verified. He thinks that an average of 90 per cent. is attainable. Owing to lack of appropriations the receipt of signals from the West Indies has been suspended. There are 145 signal stations in the United States. There is now being agitated a proposition to issue "probabilities" applicable to this coast.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's office at San Francisco.

BLACK SAND G. M. Co.—Jan. 10. Object: to work the black sands of Coos and Curry counties, Oregon. Capital stock, \$10,000. Directors—John C. Angell, Ferdinand Vassault, Mercer Otley, John Thompson and J. W. Staples.

PRIMA G. M. Co.—Jan. 10. Capital stock, \$10,000.00. Jacob S. Taber, Isaac C. Ellis, David McKay, Fred Drew and C. S. Benedict.

ONWARD G. AND S. M. Co.—Jan. 12. Location: Alpine county, Cal. Directors—H. B. Melindy, E. F. Russell, F.

its members or other persons. Directors—John J. Noon, H. J. Esdohr, John Hoffman, G. C. Clark and Timothy P. Riordan. Capital stock, \$10,000.

CALIFORNIA PORTLAND CEMENT Co.—Jan. 12. Object: the manufacture of Portland and other cement. Directors—John Mate, F. A. Brown, A. J. Eesterly, H. Fisher and C. H. Harrison. Capital stock, \$300,000.

CALIFORNIA GRAVEL M. Co.—Jan. 12. Location: Mendocino county, Cal. Directors—J. B. Wheaton, T. Howland and H. C. Swain. Capital stock, \$10,000,000.

CLARK M. Co.—Jan. 10. Location: Globe District, Arizona. Capital stock, \$100,000. Directors—S. W. Wynnam, Wm. H. Hall, James Nelson, W. H. Reynolds, C. B. Higgins.

PUGET SOUND MANUFACTURING Co.—Jan. 17. Directors—Louis Sohns, David F. Schulte, Edward P. Flint, George H. Kellogg and Wm. K. Flint. Capital stock, \$10,000.

General News Items.

GREAT suffering in India, owing to crop failures.

THEY are having severe snow storms in the Eastern States.

Great damage was done by the ice breaks in the Ohio river this week.

A SEVERE northerly gale was felt all over the State on Friday last. Little damage was done in this harbor.

THE fires in the mines at Lykens, Pa., are gradually diminishing. The loss will be smaller than was at first supposed.

TEN vessels of the fishing fleet of Gloucester, Mass., are missing, and doubtless lost with all hands.

THE *Mark Lane Express* asserts that 500 tons of fresh American beef reach England weekly. This new branch of trade has created considerable anxiety in the English agricultural districts of Shropshire and Staffordshire.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR.

GOVER.—Amador Ledger, Jan. 13: The last crushing at the old 10-stamp mill realized from \$36 to \$50 per ton. The new 20-stamp mill is now running steadily, disposing of about 40 tons of ore per day. From present indications it is expected to clean up between \$35,000 and \$40,000 monthly.

HOISTING WORKS.—The hoisting works are now completed. They are worked by water power, and are of the most approved pattern, by Messrs. Knight & Co., of Sutter Creek. The shaft is 100 feet deep, and the intention is to put it down one or two hundred feet more.

FREEMONT.—This is a new location joining the Gover on the south. Rock is being taken from the old Gover shaft and crushed at the old 10-stamp mill. The ore runs from \$10 to \$12 per ton, with a body of quartz from five to six feet in width.

BUNKER HILL.—In sinking the shaft of this mine last week a quartz lens was struck measuring five to six feet in width and the rock looks keenly.

ORIGINAL AMADOR.—This mine looks better than at any previous period of its history. We have it on good ground, and the ore now being extracted will average \$30 or \$40 per ton. The prospects are sufficiently flattering to justify the sinking of a new shaft, necessitating the putting up of fresh hoisting works, which works will be prosecuted at once.

ALL THE MINES we have mentioned above are tributary to Amador City. With the addition of the Keystone, which moves out at the old gate, grinding from its batteries \$40.00 monthly, and also the Talsman, the mill of which will soon be finished, and the extraction of ore and production of bullion commenced, Amador City is unquestionably the liveliest camp in the county, if not in the State.

AMADOR CON.—For several weeks past work has been energetically pushed in running a tunnel into the north end of the mill under the old gate, grinding from its batteries \$40.00 monthly, and also the Talsman, the mill of which will soon be finished, and the extraction of ore and production of bullion commenced, Amador City is unquestionably the liveliest camp in the county, if not in the State.

MECHANICS.—In our perambulations of the past week we paid a visit to Gopher gulch, near Sutter Creek, for the purpose of looking at the above mine. We found a pile of rock on the dump ready for shipment. It is exceedingly rich in sulphurets, with a speck of fine gold discernible occasionally. The stockholders have faith in the paying quality of the ore that they would not sell the pile as it now lies on the dump for \$8 per ton. Reaching the bottom, 100 feet from daylight, we saw sufficient to satisfy us that the reports of the value of the mine were not exaggerated. The ore is a fine, bluish, crystalline, well-defined ledge, with hanging wall of slate as smooth as glass, measured between four and five feet in width. The shaft is timbered in a substantial manner from top to bottom. About 15 men are employed, under the superintendence of Mr. Savage. If the mine holds its own, a mill will be erected in the spring.

UNEXPLORED ORE.—On Saturday the men working in the tunnel of the Montclair struck a body of quartz, which for richness dwarfs everything in the shape of gold ore we have seen in this county. Large chunks of coarse gold were scattered over every specimen. Rock of that character is estimated to yield all the way from \$1,500 to \$5,000 per ton. It is hardly in the nature of things that there should be a large quantity of such way-up ore. The owners informed us, however, that several tons of rock equal to the samples exhibited were in sight.

BUTTE.

MINING.—Oroville Mercury, Jan. 12: From Dr. A. R. Stearns, of Magalia, the former owner of the West Branch mining claim, called the Wolverine shaft, at the north end of the claim. The rock that supplies the mill comes principally from the northern part of the mine. The bulk of the unexplored ground lies in the neighborhood of the contemplated shaft.

MOOREKING RIDGE.—John Francis & Co. are at work on a ditch to bring in water from Fall Creek to turn it into the head of Know Nothing ravine, where there is a large deposit of auriferous gravel. The water will be used to wash the gravel, and can be worked without much trouble when the water is brought in. This water will cover most of the ridge below the head of the ravine and the South fork of Feather river. All along the ground has been washed in spots wherever water could be had, and it has paid handsomely in places. As soon as this ditch is completed, times will be lively again. The ditch will carry about 1,200 inches. Anderson, Priest & Co. are cleaning out the old Gaskill ditch that will carry some 300 or 400 inches. This will be sufficient to work their claim during a large part of the year.

CALAVERAS.

THE TIGER QUARTZ MINE.—Calaveras Chronicle, Jan. 13: We are in receipt of some very encouraging intelligence from the Tiger quartz mine at Rich Gulch flat. The new proprietors of the property are pushing ahead operations energetically, the developments being altogether favorable. A tunnel has been run about 100 feet on the ledge, the face of the drift being 60 feet below the surface. The vein averages about three feet in width, and of fair quality. A 10-stamp mill is being erected, which is so nearly completed that it is expected to have the battery in motion the first of next week. The mill is to be run by steam and will be first-class in every particular.

VEITH HYDRAULIC.—There is no cessation of work in the Excelsior hydraulic, Tunnel ridge. Piping is "indulged in" continuously, and labor is prosecuted with as much energy as if it depended upon the utter demerit of the gravel bank. Veith pays no attention to the scarcity of water. He uses all he can get, and when the supply fails tackles the gravel with powder. There isn't a more persevering miner this side of the Rockies than John Veith.

EMERSON HYDRAULIC.—Everything is in readiness for piling at the Emerson hydraulic, Happy valley, and operations will be resumed next week. The water is being retained. The bedrock tunnel through which the flume is laid has been lengthened a hundred feet, bringing it close to the gravel bank, and the boxes laid. The flume has also been lengthened twenty-five boxes, at the lower end, to improve the "dump." The claim is now in splendid working condition.

THE DUREYA MINE.—Everything continues to progress favorably at the Dureya mine, Chile gulch. Since the new shaft, cams, etc., were put into the mill, the machinery has run like a top, and the stamps are kept constantly in motion. No difficulty is experienced in keeping the battery supplied with water.

WATER POWER DERRICK.—Preparations are being made for the erection of a water power derrick to sink the hydraulic claim, on Tunnel ridge, to take the place of the hand machine at present in use. The necessary castings are now being made in the Sutter foundry. The motive power is to be furnished by a latest pattern hurdy-gurdy water wheel, which, together with the necessary appliances, is to be constructed and put up by Mr. John Rider, the well-known millwright and machinist. As the pressure of nearly 200 feet is available, it is expected that the derrick can be operated with eight inches of water, which will very materially lessen the present cost of running it, while its capacity will be greatly increased. The work of

putting up the derrick is to be urged forward as rapidly as possible, and when it is in running order the Veith hydraulic will be in better trim for working to advantage than any other gravel claim in the middle or southern mines.

FRESNO.

CONFIDENCE.—Valley Argus, Jan. 13: The celebrated Confidence mine, situated in Fresno county close to the head of the Fresno river, has passed into the hands of Mr. P. Carroll and J. Morton, who are going to erect a 10-stamp mill upon the property immediately, when we may look for large shipments of bullion as soon as the mill is running. This mine is expected to rival the celebrated Hite mine of Mariposa county. The shaft, which is now sunk 15 feet, has produced 500 tons of quartz which is now upon the dump, and was examined last week by a first-class mining man, who says it will yield from \$20 to \$25 per ton, and enough of the richest rock has been taken and worked through an arrastra to pay for the sinking of the shaft, and also in driving a tunnel 150 feet, to strike the vein at a depth of 175 feet.

INYO.

DEFIANCE FURNACE.—Cosmo Mining News, Jan. 13: Since our last issue Defiance has shipped 1,000 bars of bullion, leaving on hand 100 bars. This is an average of 158 bars per day. Furnace running splendidly.

LOOKOUT GOLD MINES.—W. T. Grant, one of the principal owners in the gold mines just south of the Modoc claims in Lookout, came in last Tuesday. Grant has been in the Lookout work for several weeks, upon his ledges, principally upon the Alpha, which is showing up magnificently and much beyond anything he ever expected to realize. He has worked several tons of selected ore by an arrastra process, which yielded \$220 per ton. The specimens of ore brought in by him are as fine as any we have ever seen, plenty of native gold being perceptible to the naked eye. He will return in a few days to resume the work.

LOOKOUT GOLD MINES.—W. T. Grant, one of the principal owners in the gold mines just south of the Modoc claims in Lookout, came in last Tuesday. Grant has been in the Lookout work for several weeks, upon his ledges, principally upon the Alpha, which is showing up magnificently and much beyond anything he ever expected to realize. He has worked several tons of selected ore by an arrastra process, which yielded \$220 per ton. The specimens of ore brought in by him are as fine as any we have ever seen, plenty of native gold being perceptible to the naked eye. He will return in a few days to resume the work.

The specimens of ore brought in by him are as fine as any we have ever seen, plenty of native gold being perceptible to the naked eye. He will return in a few days to resume the work.

KERN.

ANTIMONY.—Kern County Courier, Jan. 11: For a time work has been suspended on the antimony mine at San Emidio, owing to the difficulty of moving the ore from the mine to the furnaces. About a week ago Mr. Ross, of San Francisco, a practical worker in this peculiar ore, arrived at the mine from San Francisco, and after surveying the locality came to the place to procure workers for the continuation of the enterprise. The canyon will be spanned by a bridge and the ore moved on an iron track. It is intended to prosecute the work with energy, and we may soon expect great results from the new plans.

MENDOCINO.

CALIFORNIA PLACERS.—Mendocino Dispatch, Jan. 13: The mining at Cedar Creek, on the hydraulic claim, is now in progress. Water comes from an elevation of 200 or 300 feet. There are over 1,000 acres of land that are available for mining purposes. The ditch, when all completed, will cost in the neighborhood of \$15,000 or \$20,000, and will be completed sufficiently in 30 days for work to commence on the other side of Black mountain, and entirely finished in two months. There are 80 men at work now.

NEVADA.

RICH GRAVEL.—Nevada Transcript, Jan. 14: We learn that George Ragon has been taking out some very rich gravel from his claim at the head of Rush creek, near Cedar Creek. As his claim is seven ounces has been found in one pan of dirt. Last week he took out \$600 with the assistance of his little boy. This week, up to Tuesday, he had taken out \$75. A few years ago he took out \$9,000 in 60 feet of ground, near the same spot. The gravel is supposed to be the overflow from the old river channel passing through that section.

MINING SALE.—It is reported that the Murchie mine has been sold for \$100,000 to Messrs. San Francisco capitalists, and that Harvey Helen will superintend the working of the same. The mines belonging to the Murchies have laid idle ever since their hoisting works were burned, which occurred two years ago. They always paid well, and will do so again.

A LONG TUNNEL.—Grass Valley Union, Jan. 16: The Deer Creek mining company are engaged in running a long tunnel through which their claims at Mooney Flat will be worked. The tunnel is now in about 2,200 feet, and is in very hard rock. Two Ingersoll drills are kept constantly at work, and good progress is being made. When the tunnel is completed a large body of rich gold bearing gravel will be ready for the hydraulic process. Mooney Flat has the same character of gravel that has made the success of the famous Mooney Flat in Nevada county, but part of the tunnel is in Yuba.

ALASKA MINE.—Grass Valley Union, Jan. 11: The favorable reports from this new mining enterprise caused us to pay a visit to the mine to note progress. It is on the southern slope of Osborne hill, about two and a half miles southwest of Grass Valley, and in a locality somewhat famous for rich quartz and numerous ledges. The claim was owned by a miner named Mooney, who had several good crushings from it, but they found themselves unable to go to the necessary expense of putting up steam machinery, which they found was requisite after sinking a perpendicular shaft about 90 feet. The claim had lain unworked for about two years, until it was purchased by the present company, a few months ago.

PLACER.—Dutch Flat Forum, Jan. 11: The Baker claim, belonging to the Cedar Creek company, is the only claim in this section that is running. This claim is washing about five hours a day, and is advancing with its opening in an incredible manner. A bank blast, containing 100 pounds of dynamite explosive, was exploded on Saturday last. The Elmore Hill, Polar Star and Southern Cross claims are not washing, owing to the scarcity of water. The Franklin claim is ready.

AT GOLD RUN. The Cedar claims, belonging to the Gold Run hydraulic mining company (limited), is now in perfect trim. An additional shaft is being sunk, and the claim is being worked by the Indiana Hill claim, belonging to the Miners' ditch company, is fitted up in first-class style. The roof of the branch tunnel has been blasted out, an extensive rock cut run, a powder blast of 900 kegs exploded and the men laid off waiting for water. All the other claims in that district are ready.

LITTLE YORK MINES. The Empire mine is still being worked to great advantage. The supply of water, although greatly reduced, is enough yet to work four days per week.

BEAR RIVER MINES. The Centennial company have

been drifting and washing steadily with good results. The ground that they are now working is paying considerably over wages. Ritchie company have leased the lower part of their claim, to be worked on shares to D. Crissman & Co., and are receiving nice dividends therefrom. Doni Pedro company have tapped a channel through their bedrock tunnel, but the gravel found therein does not carry sufficient gold to pay for drifting.

LIBERTY HILL MINES. The Liberty Hill company are making good headway, with a large force of men and a fair head of water.

REXINGTON HILL MINES. The Rhode Island company, through means of reservoirs, obtains enough water from the gulches to grind sluice four hours per day. The Wide West company, in advancing their main drift across the channel, the air became so bad that it was found inadvisable to raise the sluice, the work on which has been progressing rapidly. The dirt taken from this mine has kept increasing in richness until it has reached \$14 to the pan.

LOWELL HILL MINES. Swamp Angel.—As the air drift connecting this mine with other diggings is completed, and has had the desired result, a large force of men are now employed, and the work of breasting out is progressing rapidly. One of the nuggets picked up in this claim last week weighed 150 lbs. The company's prospects are bright, and the Liberty Hill company are busily engaged in running their bedrock tunnels.

ST. PATRICK.—Placer Herald, Jan. 13: It is reported direct from headquarters that the St. Patrick Consolidated mining company intend commencing operations on their ledge at an early date. The St. Patrick Consolidated is an equity raised in the Pacific States, and the company is well equipped, and like the Crater will, when thoroughly opened, doubtless pay well. The western extension of the Crater, about which the owners and the St. Patrick company have been lawing for some time, has, we understand, been purchased by the St. Patrick company. This purchase will put an end to litigation in the matter, besides adding many thousands to the value of the St. Patrick company's property.

SIERRA.

LOW.—Mountain Messenger, Jan. 13: The river is as low now as it has ever been before in all the past eventful history of this historic mining town. The water has been so low for some time, that the river is low, still the Chinese are noisier and busier than most of the other townsfolk put together, mining in the river. They are buying all the old residences on Durgan flat, below W. T. Luther's, and soon will leave naught in their stead but huge piles of rock glistening in the warm sunshine. These investments undoubtedly pay, as most, if not all, the ground hereabouts prospects richly. But unless we are soon favored with some rain or snow, mining will be a dull business this year. Still the miners are most everywhere preparing to advance on the enemy's works as soon as the deluge commences.

TUOLUMNE.

RICH POCKET.—Tuolumne Independent, Jan. 13: The Pitts & Conlin quartz claim, on Experimental hill, continues to yield gold in quantities that is very flattering and encouraging to the owners. Last week, we learn, they struck another pay shute or "pocket," from which they took out, in one day, \$400. We were shown a sample of the rock, which is pure white, having a marble casing, and weighs two and a half pounds and contains \$100 in gold. From this the richness of the ore may be judged. It is a perfect network of veins and strata of quartz, dipping at every angle and threading it in every direction. The hill has not been prospected to a depth greater than 30 feet. The mining on this hill has been confined more particularly to the surface, which in many places is but a mass of crumbled up quartz, among which is found rich pieces of float.

HUNTER.—Operations at the Hunter mine are pushing rapidly ahead. The tunnel is now in, on the vein, about 350 feet, expecting to strike the shute every day. The vein is two feet thick, and the tunnel reaches a point about 300 feet below the surface. Hon. W. G. Long and parties below the mine, and they will undoubtedly develop a splendid property here. But he has been taken out of this mine that paid \$300 to the ton. This ore was obtained at a depth of 170 feet, and from the shute they are now running on.

CAVE DIGGINGS.—The new ditch, constructed by Messrs. Ghering & Ingram, is now nearly ready for use. The ditch will carry water from Tuolumne river to Cave diggings, a distance of several miles, and will be used for hydraulic mining at the same place. There is here an extensive bed of gravel of a good paying quality, but heretofore useless for want of water.

Nevada.

WASHOE DISTRICT.

JULIA.—Gold Hill News, Jan. 17: On the 1800-ft level the face of the west cross-cut is still in quartz and low grade ore. The lateral drift running south on the ore vein is showing a steady improvement, the ore giving better assays with every foot advanced.

SILVER HILL.—Sinking the main incline is making the best of progress, considering the hard character of the rock encountered and the flow of water necessary to be handled at the bottom.

CON. VIRGINIA.—Daily yield, 300 tons of ore. There is no change worth noting in any of the ore stops on either the 1400, 1500 or 1600-ft levels. The enlargement of the main drift connecting with the Gould & Curry is fast approaching completion. The main west drift from the C. & C. shaft on the 1650-ft level is in a distance of 649 feet, the face in more favorable ground. This drift will undoubtedly reach the ore vein in a very few more days.

CROWN POINT.—Sinking the main incline is making the best of progress. The 12-inch drills are doing excellent work. The rate of progress is from 26 to 28 feet per week. It is now down 1,958 feet.

OVERMAN.—The new pumping engine did not get fairly at work until day before yesterday, since which time it has done splendid work. It has already drained the water to within a short distance of the bottom of the shaft, and will soon have it dry, and in a distance ready for the resumption of work on the 1400-ft level. This is a compound, direct-acting engine, of 700-horse power, has a 32-inch initial and a 65-inch expansion cylinder, and is one of the most powerful and finest pieces of machinery ever erected on the Comstock. The attachment is direct to the bishop-head of the pump-bob, thus doing away with all the intermediate, old-fashioned double gear. A double column of 12-inch pumps extends from the surface to the bottom, which is equal in capacity to a single line of 17-inch pumps.

HOMESTEAD.—Work has been resumed during the past week in the Homestead company's new shaft. This is situated in Gold Hill, southeast from the Imperial and east of the Yellow Jacket mine. It is one of the old locations and very rich. The Homestead company are doing excellent work, and are receiving sufficient encouragement for going into more extensive and systematic operations.

CALIFORNIA.—Daily yield, 500 tons of ore. The ore stops on the 1400, 1500 and 1600-ft levels are all yielding an abundance of good ore, and never had a more promising appearance for the future than at the present time. The main lateral south drift on the 2000-ft level is steadily advancing, the drift on the 1400-ft level is also advancing. The north winze, near the dividing line between the California and Consolidated Virginia on the 1650-ft level, is being rapidly pushed ahead, the face also in rich ore. The main west drift from the C. & C. shaft on the 1650-ft level is in a distance of 649 feet, the face in more favorable ground. The appearances are that it will not take many more days to reach the ore vein in the drift.

JURICK.—Daily yield, 340 tons of ore, keeping the mills all running up to their full crushing capacities. The prospecting drifts on the 600 and 800-ft levels are opening up new and more extensive bodies of ore, while the breasts and stops on the 400, 500 and 700-ft levels continue to afford a steady and uninterrupted yield of good milling ore. The still mill is to be added to the crushing force in a very few days. The ore-producing prospects of the mine were never as promising as at this time, or the ore being milled of a better character.

LEVIATHAN. The timbering of the main north drift at

the 600-ft level being completed, the advancement of the ground being urgently pushed. An improvement of the ore has been made there, this week giving assays of from \$5 to \$128.77 to the ton; average assays \$45.20.

BALTIMORE & AMERICAN FLAT.—The northeast drift on the 1650-ft level is steadily advancing, the quartz and ore in the face still showing a steady improvement. Some of the streaks of ore in the face of this drift are very rich and give large assays in both silver and gold.

OUTRICK.—A few tons of ore are being hoisted daily from the old stopes on the lower levels. This ore is low grade, being but little better than a bare milling proposition. The prospecting drifts on the 1600 and 1700-ft levels are being prosecuted with a greater vigor and more rapid success than at any time in the past two years.

CHOLAN-PORE.—Daily yield, 120 tons of ore. The average assay value of which is \$28.50 per ton. Sinking the main incline below the 1700-ft level is making the best of progress. The bottom of the incline is perfectly dry. At the Combination shaft the big pumping engine and pumps are all ready for use when needed. There is no flow of water at the bottom of the shaft.

MIRAC.—The great prospecting drifts on the 1300-ft level are advancing in very rapid fashion. The lateral prospecting drifts on the 1405-ft level are making excellent headway.

UNION CON.—The ore in the face of the main north drift on the 1300-ft level is showing a steady and favorable improvement. The quartz vein in the bottom of the winze, which is sinking further to the southward below the same level, is also giving much better assays of both gold and silver.

CALCEDONIA.—Sinking the shaft is making the usual progress. The rock in the bottom is not as hard as it was some time since, but the flow of water is still strong and keeps the pumps very busy.

BULLION.—The north and south drifts on the 1600-ft level are each steadily advancing in very favorable vein material. The east cross-cut on the 1600-ft level is also making the best of progress, with every appearance of reaching the main ledge in a very few days.

YELLOW JACKET.—The new shaft is down 860 feet, and the ground at the bottom is dry and somewhat harder than it was last week. At the 1940-ft level of the mine the cross-cuts both east and west at the north line are being advanced, with nothing new to report. At the 2040-ft level the cross-cut, east of the foot of the south winze is in very favorable looking ground.

NORTH CON. VIRGINIA.—The strong flow of water recently struck in the west drift, on the 1100-ft level has been overcome, and work resumed with the greatest vigor in the face of both east and west drift at that station.

SOUTH COMSTOCK.—The main east drift on the 300-ft level has been stopped for the present, and the lateral drift started to the northward on the ore vein. The quartz in the face of this drift is improving.

GOLD & CURRY.—The new pumping engine is about ready to start up. The repairs to the pumping compartment of the main shaft are finished. The main east drift on the 1700-ft level is cleaned out to the face.

COSUMOROLITAS.—The upper workings still give forth their usual amount of pay ore. The drift from the bottom of the winze shows considerable improvement.

LADY WASHINGTON.—The lateral drift north from the main east drift or cross-cut, is to day in about 100 feet, still following the fine vein of quartz and low grade ore heretofore mentioned.

BUCKEYE.—The north drift on the 350-ft level has been connected with the north winze, and the extraction of ore for milling from that level has been commenced.

TRONAK.—Breasting out on the ore bodies on the 240 and 340-ft levels, is being prosecuted with all the vigor possible. The ore is of good character.

LADY BRYAN.—The cylinders, spur wheels, fly wheels, and all the larger and heavier portions of the new pumping machinery are in place.

SAVAGE.—The water is being held at a point below the 1900-ft level by the pumps, while every effort is being put forth to repair and put in good working order the connecting drift with the Hale & Norcross mine at that level.

ATREOLA AND ARGENTINA.—The shaft is down to-day to the level of 110 feet. Some little water is met with, but is easily disposed of by pumping it out through the tunnel. The character of the rock is changing to a most favorable character with every foot gained in depth, and very encouraging assays are obtained from it.

HALE & NORCROSS.—The water is held in check by the pumps a few feet below the 1900-ft level, while the connecting drift with the Savage station is being repaired and put in working shape.

BECKER.—Daily yield, 130 tons of ore, keeping the Santiago mill steadily running.

DAYTON.—The north drifts on the 500 and 700-ft levels are each steadily advancing in very favorable ledge formation.

PROSPECT.—West drift pushing ahead as usual, with the face somewhat harder vein material than heretofore met with.

SILVER CITY.—Some very good ore is being met with and extracted at the lower level, through the incline.

UTAH.—Sinking the main shaft has been suspended for a short time in order to open a station and put in another of those heavy lift pumps at the 1100-ft level.

EUREKA DISTRICT.

EUREKA CONSOLIDATED.—Eureka Sentinel, Jan. 14: At the Consolidated the rumor of an important ore body having been found was confirmed by the official letters of the superintendent, but its extent and value is "one of those things that no fellow can find out." The daily output of ore has largely increased, and the furnaces has run steadily through the week, producing about 950 bars of bullion. There are rumors of the firing up of additional furnaces, but we can trace them to no reliable source.

RICHMOND.—Furnaces running steadily the week, and there is no diminution in the supply. The main workings are all in good ore—some of it of a very high grade. Prospecting going on as usual.

K. K. CON.—The developments of the week have added greatly to the value of the K. K. and she steps into the ranks with hints of a big strike. About 60 tons are extracted and shipped daily, and the furnaces are running steadily.

ATLAS.—The connection between the new shaft and main drift was completed this week and the work of extracting ore will commence at once. The ore dump is finished and is quite imposing, towering 60 feet above the ground. All the improvements at the new shaft are very substantial.

HAMBURG.—Work still goes on, sinking the new shaft and extracting ore. There is an immense body of ore in sight, increasing in depth and width as it is developed. The company has abandoned the attempt to lease furnaces and have under consideration the proposition of building their own.

RICHMOND.—The furnaces now in operation at the Richmond smelting works are making an unprecedented run. They were started up on the 8th day of May last and have been running continuously eight months and six days, and are still in full blast. The furnaces of the company will be closed down on the first of March for the purpose of relining and the usual annual general clean-up. Work will be resumed as soon as possible, and if practicable during the same month.

SPANISH BELT DISTRICT.

TUNNEL.—Reese River Reville, Jan. 11: The two Barcelona companies, at Spanish Belt, Nye county, are pushing their joint tunnel with all the speed possible. Recently these companies purchased an Ingersoll drill, the same kind that is used in the Suro tunnel, which is now in successful operation. The superintendent telegraphs the San Francisco office that from six to eight feet per day is being run with the latter machine. At this rate of speed the ledge will be reached in less than two months. When it is cut they will be a depth of 600 feet below the surface.

The Agricultural Record of the Year.

The Californian who rejoices in the growth of his State may find many gratifying figures in the trade statistics of the year which has just closed. It was, upon the whole, a year of great activity in nearly all productive enterprises. In agriculture, in which, of course, our keenest interest is awakened, there were steps of progress of which all may be proud. The records of the trade organizations which show the amount of produce received in the city, and the records of the Custom House, which show the amounts exported to foreign ports, furnish data by which we may measure the results attained with plow and separator, with the shears, with the wine press and with vat and churn.

Let us note, first, the production of the leading cereal. The copious rains of last winter and the extent of land under the plow, set our statisticians fairly wild in their early estimates of the surplus of wheat we would have for export. It soon became apparent that their lines were overdrawn, and yet the result is grand enough. It is shown by the receipts reported by the Produce Exchange that there were shipped from the interior to this city 10,516,913 cts. of wheat. In 1875 there were received 7,676,007 cts. Our gain this year is, therefore, 2,840,906 cts. Of flour the receipts from our mills were 519,114 bbls., in 1875, 491,408 bbls.; a gain this year of 27,706 bbls. The Custom House records show the exports of these articles. We sent abroad in 1876 9,920,117 cts. of wheat, and 506,974 bbls. of flour; in 1875, 7,546,207 cts. of wheat and 467,719 bbls. of flour. The gain this year in export was, therefore, 2,373,910 cts. of wheat, and 39,255 bbls. of flour. The total value of wheat and flour exported during the year was \$18,564,525. This is a gain of \$2,000,000 in value over the value of 1875.

In barley there is also a notable percentage of gain. The receipts in 1876 were 1,626,066 cts.; in 1875, 988,280 cts.; an increase this year of 637,786 cts. The exports of this grain have grown in a more rapid percentage than the production. In 1876 the exports were 350,022 cts.; in 1875, 125,158 cts.; an increase this year of 224,864 cts. Our barley has this year been brought more prominently to the attention of Eastern brewers than formerly and there was for a few weeks quite a brisk movement both by rail and sea. The advance of railway rates, just as the movement was fairly started, embarrassed the shippers and reduced the trade. Then it was that we saw barley shipped around the Horn to New York, to be re-shipped by car to St. Louis, because all this distance could be compassed for less money than the 2,000 miles of rail hence to St. Louis.

As all our shepherds know to their sorrow, the wool trade of the year was exceedingly unfavorable, and both clips came upon a dull market. Thus, although the grand totals of amounts of wool produced take their place in the columns of increase, the low rates received detract greatly from the satisfaction which might have been felt over the result. Last week we gave the complete figures in wool, but in this connection it will be well to repeat that the total shipment from the State by land and sea was 52,633,923 lbs. In 1875, 48,183,017 lbs. were exported. This shows an increase to the amount of 4,450,906 lbs., but the low prices prevailing reduced the increase in value to a low figure.

The increase in dairy production during the year is quite notable. The dairy has been carried into regions which were formerly thought unfitted for it, and there has been a tendency to increase of cowage in the older dairy counties. The figures as compiled by Mr. Stone, the statistician, show that the receipts of butter during the year have been 10,927,200 pounds. In 1875, the receipts were 9,551,500 pounds, an increase this year of 1,375,700 pounds. The receipts of cheese were 7,017,300 pounds; in 1875, 6,021,000 pounds; an increase this year of 996,300 pounds. From these data, with estimates of the value of the commodities, it is safe to say that the aggregate value of the dairy products received in this city during the year was \$4,500,000. This indicates that our dairy industry is of no mean importance, as it can show a produced value of one-half the value of our famous wool clip, and one-quarter the value of our wheat and flour surplus, which gives us a reputation all over the world. The year has closed with butter and cheese at much lower figures than were common, but the present prospect is that this will find compensation in the coming months. The drouth, if continued, will prove serious to many of the interior ventures, and will restrict the weight of production to the northern coast and the ranches on the river low-lands.

In other lines of agricultural production, the year has some points of increase and some of decrease. The production and export of green fruits has been much larger than heretofore. Raisins have been numbered by the ten thousands of boxes. On the other hand, the wine export

has shown but a very narrow margin of increase, only a value of \$6,460 over the record of 1875 being recorded. Hides, which years ago were almost the sole article of export from this coast, are now yearly decreasing in amount, and leather is also figuring in smaller numerals. Thus the usual course of productive growth is followed by our State as it changes more and more from the lower to the higher agricultural arts.

Aside from agriculture, the productive industries of our State and coast show praiseworthy results. The production of the precious metals for the coast has increased from a value of \$80,889,037 in 1875 to \$90,875,173 in 1876. The coinage of our mints shows a total of \$32,069,000 in 1875 to \$42,704,500 in 1876.

Not the least favorable deduction from the figures of the year is that we are growing in the line of independence, and our home production is satisfying the needs of our people. The Custom House figures show that the duties collected on foreign imports were, in 1875, \$8,131,637, and in 1876, \$7,817,736, a decrease this year of \$313,901. At the same time the gross value of our exports was \$73,463,250 in 1875 and \$80,421,971 in 1876, an increase of \$6,958,721. Reducing our expenditures for foreign goods and at the same time increasing our sales of produce for export, is throwing the balance of trade more and more in our favor and storing up a surplus of wealth among our own people. This movement can continually go on if our men of wealth will but do their State the justice of patronizing home industries and if those in charge of productive enterprises will do justice to our splendid conditions of soil and climate and produce wisely all that it enters into the mind of our citizens to desire.

Moore's Flat Gravel Mines.

The Nevada Transcript has been shown a very complete and finely executed map of the mining section in and about Moore's Flat, drawn by Surveyor Fen Miller. It shows the mines, gravel beds, bedrock lines, ditches, streams, roads and villages along the lines of the ancient blue lead leading from Forest City and Minnesota, in Sierra county, to Snow Point, in

Nevada county, and along the line down as far as North Bloomfield. It gives the location of every mine and every mining claim on the route, all the levels from point to point, and shows the incline or pitch of the channel, and other details. It is a very finely executed and valuable production. It shows among others the following locations between Snow Point and the grounds of the North Bloomfield Co.: Cowger & Co., Wand & Blackwell, Curtis & Co., New York Co., Consolidated Co. Nos. 1 and 2, Centennial Nos. 1 and 2, Emigrant Blue Gravel Co., American Consolidated, Moore's Flat Blue Gravel Mining Co., Little Giant, Shanghai, Purcell & Tunney, Shay & Co., Central Co., Dead Wood, Illinois, Eagle, Nevada, Blue Banks, Boston, Independent, Monumental, Franklin, Blackburn & Co., Watt & Co., Long & Atwood, etc. Some of the claims on the west rim of the supposed channel, at Moore's Flat, are extensively worked, and are rich and pay splendid dividends, but a majority of them are as yet barely prospected. The work of regular development is now going on in several places to open claims, and on most of them more or less work is being done each year. The Moore's Flat Blue Gravel Co., Sid. Hunt Superintendent, is sinking a shaft at a point about half a mile southeast of the town of Moore's Flat, on the side hill. It is expected a depth of about 400 feet will have to be reached to strike the bedrock. The finest hoisting works in the county have been erected there, and a large shaft of three compartments is being sunk. It is timbered up in the same substantial manner as those of the California and other mines on the Comstock. A tunnel is also being run to tap the shaft at a point 200 feet below the surface for drainage. The tunnel will be about 1,000 feet in length. The work is being pushed ahead as rapidly as possible. The company owning the claims is a wealthy one, and the Superintendent is a thorough and practical miner. This claim is located about one and three-quarter miles below Snow Point, on the line of the channel. The Nevada company, a little further down, are running a tunnel to tap their claim, which will be over 2,000 feet in length when completed, which will allow all their ground to be washed through it, and will afford outlet to other claims back of them, when their ground is worked out. Watt, Dibble & Co., are sinking a shaft on their claim, which is located about four miles below Snow Point, on the north side of Bloody Run creek, and which

covers an area of over two miles on the line of the channel. It is expected they will have to sink about 300 feet to get to bedrock. Other work is also being done on other claims on the line. Most of the ground is so located, that it will have to be worked by drifting, which is regarded by many to be as profitable a way as any other; particularly where the banks above the channel are of such great depth as they are on this channel. The developments being made by these companies will soon demonstrate the great value of that district, and will induce capitalists elsewhere to seek it for profitable investment. It is generally acknowledged by all who know anything of the section of our country from Snow Point to French Corral, that it is the most extensive and richest mining region on the coast. The developments mentioned above will only add further testimony to the fact, and help to make it more generally known elsewhere.

Abies Venusta.

In the vegetable kingdom the conifers bear a markedly high and deserved rank, but none more so than the *abies*, or fir family. One variety of the *abies* is found alone within the borders of San Luis Obispo county, and is so rare that, until quite recently, but one specimen was to be found in all Europe. So rare is a knowledge even of this beautiful tree that we have heard but two persons mention it in our two years' residence in San Luis. These gentlemen were Dr. W. W. Hays and Mr. Ernst Krebs. Mr. Krebs has spent large sums of money to obtain specimens, but has never succeeded in getting healthy ones until the present week, when he received seventeen fine young plants. The foliage resembles, slightly, the common firs of the forest. It is far more delicate, the leaves longer and not so crowded upon the limbs, which are slender and graceful. The upper side of the leaf is a deep bright green, while the under surface is striated with silver, white and pale sea green, perfectly beautiful in their delicate blending. It is said to be the most beautiful object among all California's forest treasures, and when the wind puts in motion its airy branches is said to resemble undulating waves of

silver foam. From these young specimens in the grounds of Mr. Krebs, we can imagine what a forest would be where the spiral trunks rear themselves to a height of 50 or 60 feet, and are clothed with a profusion of its delicate foliage.

The habitat of this treasure is a circumscribed spot of a few acres in the deep recesses of the Santa Lucia mountains, on the border of Monterey county, and so inaccessible that but few, even of the hardy hunters, have ever seen it. This is said to be the only spot in the known world where the tree is found. In the early days of California the padres used to send Indians to gather the resin that exudes from the trees where scarified by accident or design; and this resin was burned in the censurers before the high altars upon great occasions. From this fact it derives the local name of "Pinabeta de los Padres." Mr. Krebs has made arrangements to have a supply of seed gathered next season, and will, we hope, be successful in introducing it into common cultivation.—*San Luis Obispo Tribune*.

RAINFALL AND FORESTS.—Mr. Meehan, of the *Gardener's Monthly*, is evidently an infidel on the rainfall-forest faith. He says: "Our European friends are finding some curious 'facts' in regard to rainfall and forests. In France, a Mr. Faurat found that there was much more rain fell in a forest than on a sandy plain not a great way from it. It so happened, however, that another forester kept an account in a forest about the same distance from the sandy plain, and the figures do not agree. Most persons would have suspected an error in ascribing much influence to the forests, but these two fell to discussing the nature of the forests themselves; and now it is asked of us to believe, that while ten per cent. more rain will fall on a pine forest than on a sandy plain, only five per cent. more falls on an oak one. The only wonder is that 95 per cent. should fall on the treeless plain."

ROOFING POMPEII.—Among the various propositions made to the Italian government is one by a society of Italian and foreign capitalists, to put a roof, composed of glass and sheet-iron, over the whole of the ruined town of Pompeii. This is necessary on account of the constant decay which the frescoes and the walls are undergoing. All that the company asks is that the admission fee be increased, and that extra tax be given to them for a certain number of years.

The Isthmus Canal.

Last week we alluded to the fact that a decision had been handed to President Grant in favor of what is known as the Nicaragua route for the isthmus canal. As this is a matter of such deep interest to the industries of our coast and now seems nearer realization than at any former time since the project was broached, we have prepared a little engraving showing the route along which our produce may soon be speeding to the European markets. By this engraving the following report of the commission may be better understood:

To the President of the United States—Sir: The commission for the United States appointed by you to consider the subject of communication by canal between the Atlantic and Pacific oceans, across, over, or near the isthmus connecting North and South America, have the honor to submit, in advance of their more elaborate and final report, containing data for their conclusions, and after a careful and minute study of the several surveys of the various routes across the continent, the following unanimous report:

First. That the route known as the Nicaraguan route, beginning on the Atlantic side at or near San Juan de Nicaragua, known to Americans at Greytown, running by canal to the San Juan river, following it by slack water navigation to Lake Nicaragua, across that Lake to Rio del Medio, and thence by canal to Rio del Brito, on the Pacific coast, possesses, both for construction and maintenance of a canal, greater advantages, and offers fewer difficulties from engineering, commercial and economical points of view, than any one of the other routes shown to be practicable sufficiently in detail to enable a judgment to be formed of their relative merits.

Second. That the summit level of this route to Lake Nicaragua is designed to be kept at a permanent height of 108 feet above the level of the sea. This height is to be overcome in the Atlantic slope with four dams in the San Juan river and ten lift-locks, and in the Pacific slope with ten lift-locks.

The total distance from the Greytown end to that at Brito is 181 33-100 miles. Of this distance the Atlantic slope division from Greytown to San Carlos, at Lake Nicaragua, comprises 108 5-10 miles, of which 63 miles are by slackwater navigation, and 45 5-10 miles by canal. The summit level division comprises 56 5-10 miles by Lake Nicaragua from San Carlos, at the head of the San Juan river to Rio del Medio. The Pacific slope division comprises 16 33-100 miles by canal from the mouth of the Rio del Medio to the mouth of the Rio del Brito. The dimensions of the locks proposed are 400 by 70 feet, with 26 feet depth of water. Artificial harbors must be constructed at Brito and near Greytown, and although that at Greytown presents unusual features, requiring careful study and skillful treatment, there is no question of its practicability.

Third. That the cost of construction of this canal and harbor, with all the necessary adjuncts, will be at least \$100,000,000, and that the cost by any other route will greatly exceed the cost by this route.

Fourth. That after all the preliminary arrangements have been made, the time required for actual construction should not exceed 10 years.

Fifth. That an interoceanic canal across this continent should be under the protection of all nations interested, and that they should guarantee not only the neutrality of the canal, but also of a contiguous strip of territory on each side of not less than 50 miles in breadth, and of ocean approaches for a distance of not less than 100 nautical miles in any direction along the coast and out seaward from each end.

The prospects for an early commencement of the work are considered extremely favorable. Under the direction of the President the principal maritime powers of Europe have been severally addressed upon the subject of the canal, the satisfactory results of the surveys which have been made, and also the views embodied in the above report as to the best route. Answers have been received from some of the governments, in which they express themselves favorable to an early prosecution of the work, and admit the wisdom of according it an international character by an equal participation in its construction, and in the maintenance for it of an inviolable neutrality. As soon as the views of all nations communicated with have been received the President contemplates submitting all the papers and correspondence in a special message to Congress, in which he will urge that the United States take the steps necessary to the inauguration of this great enterprise.

In lighting fires in stoves likely to smoke, first warm the chimney or its contents by burning a handful of shavings or paper on top of the coal.

A Curious Mining Machine.

Some two months ago a couple of gentlemen named B. Hedge and O. N. Walker came from Augusta, Maine, to Oronville, and after spending a few days looking around, began the construction of a boat on the banks of Feather river, just below the bridge, and but five minutes, walk from the business part of the town. There was nothing peculiar about the boat or barge, except its size, it being probably 40 or 50 feet in length, and perhaps 20 in width. The top of it was boarded over and it made a large platform. The space between decks was about three feet and unoccupied. By the time the boat was completed, a steam engine and an iron pipe 26 feet in length and about 30 inches in diameter, were on the ground and ready for use. The story now came out. These gentlemen were going into the business of mining by a new process. We will describe it as it now is, and every man, woman and child in Oronville will tell you the same story, for they have seen the new machine work. As we said before, the pipe is 26 feet in length, and made of thick iron—hoiler iron, we think. At the bottom is a valve, or trap-door, which opens both ways, inward and outward, but is prevented from opening in the latter direction by a latch, until the operator desires to have it opened, and then all he has to do is to remove the latch or spring and the valve opens. This is all at the lower end. Half way up to the top is another valve; that is, a round hole six or eight inches in diameter has been cut through the tube or pipe, and a cover fitted to it so as to close air-tight. The cover is hung on hinges, and opens and shuts with the slightest movement of the pipe. Its use will be seen further on. The top of the pipe is covered by a round iron covering, which is securely fastened in its place. Through this top runs an iron pipe an inch or more in diameter, on the top of which is a valve; the pipe is half as long as the large pipe, and the lower end of it is filled with small holes. There are also at the top, or near it, of the large tube or pipe, two small holes, into which are fitted pipes, one from the boiler and the other from the pump. By means of a mast or crane, with blocks and tackle operated by the engine, this large pipe is suspended in the air by a bale, the lower end a few feet from the side of the boat and two or three feet above the water. The engineer puts on steam, and the pipe, of its own weight (for it weighs 2,000 pounds) begins to sink into the river. The lower valve opens inward, and the pipe fills with water until the bottom of the river is reached. We will say the water is eight feet in depth. Of course there will be eight feet of water in the pipe, and all above it will be full of air. Now for the novel work. The engineer forces the pipe full of steam, which drives the air out of the large tube into the small one inside, whence it escapes out of the top through the valve. The upper part of the large tube is now full of steam. One cubic inch of water makes 1,728 inches of steam. Now, by means of the pipe from the water pump, a stream of water is thrown in upon this steam, which instantly is condensed, leaving a vacuum, but only for an instant, or rather a space of time so short that it cannot be noted, for up comes the earth from the bottom of the river and fills the pipe, which is then raised by means of the engine, the bottom valve opened outward, and down slides the muddy mass into a boat, where it is washed and the gold taken out. This pipe can be lowered and raised inside of a minute, and bring up each time from two to four tons of earth, stones and everything else beneath it. The atmospheric pressure is 15 pounds to the square inch. As soon as the pressure is removed by making this vacuum, up comes everything beneath pipe except the bedrock itself. Everything about the machine is plain and simple. There is nothing in the work to get out of order that we can see. One can see when the pipe fills with earth, for it suddenly shoots downward a foot or two. A patent has been obtained in this country, England, and some of the South American States. It was originally intended for cleaning out rivers where mud banks had been formed, but it was thought best to try it in our river beds as a mining machine. So far it works well.—*Oronville Mercury.*

CLEANSING OLD IRON WATER PIPES AT ELGIN.—A short time ago the commissioners of Elgin resolved to cleanse the old iron water pipes, and relay them in those parts of the town where they would be of use. The first portion of the pipes (which had been in the ground for more than 20 years, and were much incrustated) has now been cleansed. The process was gone through at New Elgin, where a rough furnace was erected to meet the object in view. The pipes, two at a time, were laid into the furnace, and subjected to an intense heat for about half an hour. The action of the heat loosened the incrustation of the pipes, and when the pipes were lifted out of the furnace the greater portion of it at once fell off. The most troublesome portion of the work, however, remained to be done. The pipes had to be cleaned with a spring scraper, made to exactly fit the size of the pipe. After undergoing this work, the pipe was allowed to cool till it was in a fit condition to be dipped into a "well" some 12 feet deep, containing Smith's patent solution, where it remained for nearly a minute; after which it was taken out, and presented all the appearance of a new pipe. By the adoption of this process the town will, it is said, be £300 richer than if the old pipes were sold as mere metal, and new pipes bought to replace them.—*Ironmonger.*

USEFUL INFORMATION.

Fire-Proof Shingles.

A writer in the *Polytechnic Review*, says a gentleman in Philadelphia has effected arrangements for practically introducing upon a large scale an extremely simple and excellent process for impregnating shingles with antiseptic and noncombustible substances, the immediate object of the process being to prevent the destruction of the shingles by rot, and to render them proof against fire under ordinary contingencies. Concerning the great utility and value of a process of this kind which will fulfill in practice the promises of its advocates, there can be no difference of opinion. Shingle roofs have always been extremely popular, as the enormous annual consumption of timber in their production indicates, but the advantages which they possess on the score of cheapness and excellence is materially affected by their liability to take fire at the slightest cause, and the rapidity with which they deteriorate, by decay or rot, under the influence of the weather.

The annual consumption of shingles in the United States at the present time has been estimated at about 4,000,000,000, of which doubtless, not less than 75 per cent are demanded to replace those destroyed by fire or rendered worthless by rot. It will, therefore, be apparent that these two elements of mortality entail upon the country at large an enormous annual loss in dollars and cents, to say nothing of the loss arising from the communication of fire to neighboring buildings, which, in many instances, may be directly traced to the same cause.

The expedients that have heretofore been practiced to obviate or lessen these dangers and disadvantages, consist mainly in the liberal employment of paints or whitewash, which, in addition to being expensive and troublesome, are only partially, or at best, temporarily effective. By the process which Mr. Smith employs, the shingles are submitted to the action of antiseptic and non-combustible chemicals, until through saturation is effected. This treatment insures the effectual coagulation of whatever of the decomposable sap matters remain in the wood, and so completely impregnates the fibers with mineral matter, that their ignition from all ordinary causes of accidental fires, such as sparks from locomotives, flying cinders from burning buildings, etc., is rendered impossible. At the same time the texture of the shingles is rendered denser and harder. A burning chip of wood, or glowing coal, placed in contact with the surface of one of the prepared shingles will simply carbonize the wood, at the place of contact, but will not inflame it. As a preventive against fire, therefore, the process in question is obviously of great practical value. The removal or the conversion of any aluminous matters that may remain in the wood into insoluble compounds with the antiseptic chemicals employed, on the other hand, is an equally effectual and valuable preventive of rotting.

From the inventor's published statement, the cost of the prepared shingles will not prove to be an objection against their general introduction, but will, on the other hand, prove to be one of their strongest claims to public favor. At the present time the wood used for the better (because more lasting) qualities of shingles is cypress or cedar, and requires to be carefully selected and seasoned, and are sold at a much higher price per thousand than the commoner sorts made from spruce, hemlock or pine. The process of Mr. Smith permits of the use of the hemlock, pine, spruce, chestnut, poplar, or other common sorts of wood, and by virtue of the imperishable and fire-proof qualities which it imparts to them, renders these materials more durable and vastly safer than the more expensive materials usually employed. The actual cost of the treatment is admitted to be quite small, and the prepared shingles are available to the public at a price notably cheaper than they are at present charged for the better grades of ordinary shingles, the inventor's statement being to the effect that they can be sold at a cost of one-third the price of good cedar shingles.

The Manufacture of Woolen Hats.

But few of our readers are acquainted with the processes involved in the manufacture of woolen hats. The *Philadelphia Trade Journal* is enabled to furnish the following details through the courtesy of two prominent Reading firms. The processes are as follows: The wool is first thoroughly cleansed by immersion in hot water; it is then wrung out and placed in a drying room to dry, after which it is passed through a picking machine, making 900 revolutions per minute. The wool being thus prepared, is next fed into a carding machine, which turns out 20 dozen double bodies per day. Each body is cut in two, each half forming an entire hat. These half bodies are next passed through a felting process, by the aid of steam, which renders them more compact and of a denser fiber. They are then placed in a hoghead and boiled for two or three hours, and are then tied up in linen rags and passed through the fulling and sizing machine, then soaked in cold water to remove the vitriol, which would otherwise turn gray; from thence they are blocked and returned to the soak for one night for the same purpose, after which they are placed in the coloring tank, then reblocked, as the coloring process brings them to their original shape. They are then placed in the drying-room to be made ready for

stiffening, which is done by the aid of glue and Irish moss. (One of the firms now uses shellac.) They are then put into another drying-room, from whence they are taken, ironed, trimmed and packed in pasteboard boxes, one dozen of a given size in each box; these boxes are in turn placed in wooden ones, one dozen in a box, making a total of one gross in each. This is the way in which these well-known firms manufacture upwards of sixty dozen hats per day, aided by the most expert workmen.

The Rates of Postage.

Postal cards, one cent each, go without further charge to all parts of the United States and Canada; with an additional one-cent stamp they go to all parts of Europe.

All letters, to all parts of the United States and Canada, 3 cents per half ounce.

Local or "drop" letters, that is, for the city or town where deposited, 2 cents if delivered by carriers, and 1 cent where there is no carrier system.

Newspapers, daily, semi-weekly, tri-weekly and weekly, regularly issued and sent to regular subscribers, 2 cents per pound, payable at the office of publication; newspapers and magazines published less frequently than once a week, 3 cents per pound.

Transient newspapers, magazines, pamphlets and handbills, 1 cent for each two ounces or fraction thereof. Single copies of the Presses weighing less than two ounces, the postage upon irregular numbers is 1 cent each. All other miscellaneous matter, including unsealed circulars, books, book manuscripts, proof-sheets, photographs, etc., and also seals, letters, balls, and roots, and merchandise not exceeding four pounds in weight, 1 cent for each ounce or fraction thereof.

The following are the postal rates with Europe. The rates for letters are for the half ounce or fraction thereof, and those for newspapers for four ounces or fraction thereof:

To Great Britain and Ireland, letters 5 cents; newspapers 2 cents; France, letters 5 cents; newspapers 2 cents; Spain, letters 5 cents; newspapers 2 cents; all parts of Germany, including Austria, letters 5 cents; newspapers 2 cents; Denmark, letters 5 cents; newspapers 2 cents; Switzerland, letters 5 cents; newspapers 2 cents; Italy, letters 5 cents; newspapers 2 cents; Russia, letters 5 cents; newspapers 2 cents; Norway, letters 5 cents; newspapers 2 cents; Sweden, letters 5 cents; newspapers 2 cents; Turkey, European and Asiatic letters 5 cents; newspapers 2 cents; Egypt, letters 5 cents; newspapers, 2 cents.

For Asiatic countries, the half ounce limit for letters, and the four ounces for newspapers, still holding good, the rates are:

To Australia, letters, via San Francisco (except to New South Wales) 5 cents, via Southampton 15 cents, via Brindisi 21 cents, via San Francisco 2 cents, via Southampton 4 cents, via Brindisi 8 cents; China, letters, via San Francisco 10 cents, via Southampton 27 cents, via Brindisi 33 cents, newspapers 2, 4 and 8 cents, by the respective routes; British India, letters, via Southampton 21 cents, via Brindisi 27 cents, newspapers 4 and 8 cents respectively; Japan, letters, via San Francisco 12 cents, via Southampton 27 cents, via Brindisi 33 cents, newspapers, via San Francisco 2 cents, via Southampton 4 cents, via Brindisi 8 cents.

ECONOMY DUE TO EMPLOYERS.—"Waste not, want not," is a grand old proverb. "He that is faithful in little is faithful in much." It is true enough that a person who takes no care of materials committed to his hands by an employer, will not be careful of his own property. Economy and wastefulness are habits that will influence us, whether with our own substance or that of another. As a rule, the man or boy who takes care of his employer's goods will be likely to look after his own, and is on the road to prosperity. Some men are worth much more than others, simply because they waste nothing. If an employer be wealthy, and stock abundant, that is no excuse for waste or carelessness. Loss is loss and robbery, whether it be in much or little. It is forcibly said that "Heaven allows nothing to be destroyed." There has not been a single drop of water wasted since the creation. The decomposed elements of the past autumn will supply aliment for the next spring. Economy, rigid economy, is one of the laws of Nature; and we shall not realize the "good time coming" until we are careful and economical.

GOOD HEALTH.

Wearing and Washing Flannels.

We read in *Hall's Journal of Health* that the very best thing that can be worn next the skin, in summer as well as winter, is common woolen flannel. One color has no advantage over another, except that white is more agreeable to the sight. Recent scientific experiments, carefully conducted, prove the truth of the popular sentiment, that woolen flannel is the best fabric to be worn next the skin, as it absorbs more moisture from the body than any other material, and by so doing, keeps the body more perfectly dry. Cotton absorbs the least, hence the perspiration remains more on the skin, and being damp, the heat of the body is rapidly carried off by evaporation and suddenly cools when exercise ceases, the ill effects of which no intelligent mind needs to be reminded of. Hence it is that the common observation of all nations leads them to give their sailors woolen flannel shirts for all seasons and for all latitudes, as the best equalizers of the heat of the body.

We believe it to be one of the most difficult things about the house to properly wash flannels so that they will neither shrink nor full up and become hard. Mrs. Beecher has a talk in the *Christian Union* about this, as follows:

Cut up what soap may be needed, and dissolve in a skillet of boiling water. Let it stand on the stove and simmer till every particle is dissolved. Never rub soap on the flannels or allow a bit to settle on them. Nothing "fulls" flannel so badly as rubbing soap on it or letting bits of it settle on the cloth. A place on which a bit of soap has lodged or been rubbed will have a different shade from the rest when dried, making the whole garment look spotted.

Take a small tub, not quite half full of scald-

ing hot or boiling water. Into this pour enough of the dissolved soap to make a rich suds, pour to this some ammonia, prepared from "concentrated ammonia"—a tablespoonful and a half to 10 or 12 quarts of suds is a fair proportion. Stir this and the soap into the hot water till it is all thoroughly incorporated. Then put in the flannels. Two or three articles are quite enough to soak at one time. Press them well under the water, but turn them over in the water occasionally while they are soaking. Let them remain in the water till it is cool enough to put the hands in without discomfort. While washing keep a good quantity of water at boiling heat on the range for rinsing purposes and to keep the suds as hot as it can be used. Before one piece is washed and ready to be wrung out, fill a small tub half full of clear hot water. Into this stir a little more "blueing" than would be used for cotton or linen. Shake out each piece as soon as washed quickly, and throw at once into the hot rinsing water.

Rub the flannel as little as possible, but draw it repeatedly through the hands, squeezing rather than rubbing. Harsh rubbing thickens and injures the fabric. Never wring with a wringer, as the pressure mats the nap down so closely as to destroy all the soft fleecy look of good flannel. Wring with the hands as dry as possible, then rinse and wring out again; and when as dry as it can be made by hand, snap out, stretch and pull out into the true shape; dry in the open air, if possible. Bring in when not quite dry, roll up a short time, and iron while still a little damp, so that each part can be more readily brought into shape. Pressing when ironing is better for the flannel than rubbing. It does not make the fabric feel so hard and wiry.

Scarlet flannel is poisonous to some skins if used before washing, and as one is not always sure how one may be affected by it, it is safer to give it a scald in hot water with a little soap—not enough to make a strong suds. Let it stand and soak a few minutes, then wring out and treat like other flannels. The smell of new red flannel is not agreeable to many, and for this reason it is desirable to wash it before using. But no washing that we have any knowledge of can keep red flannel looking nice if used for underwear for any length of time, unless worn by people who do not perspire freely. It becomes badly discolored and spotted in most cases. Washing red flannel before making up will "shrink" it as much as is desirable.

Useful and Healthful Children.

A lady writes for the *New York Tribune* as follows: The great effort of many parents seems to be to surround their children with bulwarks against want and trouble that they may be in a measure secure from a large part of the ills that flesh is heir to. The father is unwilling that his children should struggle against overwhelming odds as he has done, should toil and economize and plan and fight as he has had to do, and he fancies that investments in real estate and a balance in bank will be the best inheritance he can leave them. So he denies himself indulgence in even necessary things that he may save and make for his family. The mother, remembering how irksome household tasks were to her in her girlhood, permits her daughters to lead lives of domestic ease and indolence, thinking that in so doing she makes the best manifestation in her power of maternal love. As a natural consequence of this view on the part of parents, we see growing up all around us young men and women perfectly useless for all the practical purposes of life, mere hot-house plants, that under glass and with proper conditions of moisture and temperature thrive luxuriantly, but so tender and helpless and unprovided against adversity, that one blast of the north wind freezes them to the core, withers all their activities and paralyzes all their faculties; or if they take heart of courage and battle against misfortune, they are so ignorant of the use of the weapons they must handle, that the fight goes against them.

There is only one way of making the muscles firm, hard and strong; food, of course, is necessary, so is rest, but more vitally important than either is vigorous exercise, and this each owner of muscle must take for himself. Just so of intellectual and moral fiber. It is built, not from without, but from within, and is the result of independent thought and action. The sooner a boy can be made to wait upon himself, to think for himself, to act for himself, the sooner will the germs of true manhood begin to develop within him. It is no kindness to surround him with such attention and care that he will not be compelled to learn the lessons of self-reliance, of patient industry, of persistent hope. There is profound wisdom and philosophy in the exhortation of St. Paul to "rejoice in tribulation," not because it is a pleasant thing to the soul, but because it develops strength, and brings to the individual exercised thereby a consciousness of power and an ability to use it that could not be otherwise attained. As well might the giant oak complain of the storms and tempests that have been its ministers of strength and growth, as the soul, mighty in capability through conflict and disaster and victory, complain of the dust and struggle of the battle-field, whence its spoils were won. The real crowns of this world are crowns of labor. Happy are they who rejoice in discipline, in adversity, in struggle, and accept as the crowning blessing to the race in its present fallen condition, "Cursed is the ground for thy sake; in thy sweat thou shalt eat bread."

Continued from page 34.

them, I think it will create a great deal of dissatisfaction. I don't want to give my proxy to vote for any such thing. Let the men who are present vote their own shares on this question, and not those of their proxies. That would be unlawful and create general dissatisfaction.

Mr. Heydenfeldt—We have been here a long time, and are tired out. I am willing to pass anything the gentleman wants if he will complete his labors and let us go home. As a matter of course, nothing that is passed here is binding upon the trustees. The stockholders delegate their power, and their only remedy is to take care whom they elect. These resolutions are simply mandatory to the attention of the board, and they won't obey the directions unless they choose to do so. They have been selected on account of their knowledge, ability and skill to manage this business. They know how to manage it, and the stockholders don't know how. At best the resolutions are but advisory.

A Voice—I move to lay the resolution on the table.

Mr. Mackey—Mr. Dewey says that the assessor at Virginia informed him that a mill would pay for itself in two or three months. Now I would like to know from whom he got that information. Whoever told you that, it is not true. No mill can be cleared short of a year or 18 months. Then we must consider the risks that are to be run of the property being destroyed. You cannot build a mill that will crush 300 tons of ore for less than \$450,000 or \$500,000. There is a great deal of talk about

Tailings.

We will sell them if anybody wants them. These tailings ran to waste in the Carson river for 10 or 12 years, until Mr. Hobart and myself conceived the plan of running them down to Big Flat and saving them. The plan cost \$130,000. My object in taking them down was, as I have a very large family, to give them to the little fellows to work when I am gone.

Some further opposition to the resolution was made, when Mr. Heydenfeldt said: "Since all the stockholders are against you, Mr. Dewey, you had better withdraw your resolution."

Mr. Dewey—I think not. I shall pursue my remarks.

Mr. Heydenfeldt—Well, withdraw the proxies and vote so.

Mr. Dewey went on to explain his resolution, and in the course of his remarks stated that \$13 per ton was charged for milling Con. Virginia ore.

Mr. Mackey—We don't charge anybody \$13 a ton. We used to when quicksilver was high. For the last four or five months we have charged only \$12.

The resolution was lost.

Thanks to the Management.

The following resolution was presented by Robert Sherwood:

Resolved, That the thanks of the shareholders are due to the trustees for their efficient management during the past year.

This resolution was adopted, and the following stronger one presented by E. C. Platt:

Resolved, That all the matters and things, acts, contracts, transactions and disbursements made and entered into, agreed upon or executed by the Board of Trustees during the past year be, and the same are hereby ratified, approved and confirmed.

After some very angry and heated talk this resolution was also adopted, and shortly after the meeting adjourned.

Oil Refining in California.

The Los Angeles *Herald* speaks as follows of the oil interests of southern California and the progress of refining:

The present development of the oil interests of Los Angeles county will render interesting some notes of the progress of refining hereabouts. About four years ago a refinery was established in the San Fernando oil region by a stock company. It was placed under the charge of a superintendent named Smith. This gentleman could not get a satisfactory percentage of light oil from the heavy crude product. About 18 months ago the refinery passed into the hands of Messrs. G. D. Scott and Baker. These gentlemen were a little more successful than Mr. Smith had been, but they also failed to secure the best results. They were succeeded by a Mr. Shoemaker, of Akron, Ohio, with a like record of failure. Determined to make a success of it next time, Mr. J. A. Scott, a noted refiner of the Pennsylvania oil regions, was sent for, and his handling of the refinery was attended with entire success. He remained in the San Fernando district until his presence was called for at Ventura, to take charge of the California Star oil refinery.

Mr. Scott, we are now informed, is turning out of the works there some 20 barrels of refined oil daily, with very limited facilities. The gross product of the Ventura wells and springs is about 80 barrels of crude petroleum a day. The wells there are down to a depth of about 140 feet. At San Fernando there are five producing wells, and the gross product of crude oil daily is about 40 or 50 barrels.

It should be stated that the oil of the San Fernando district is of a much finer grade than the Ventura article. It refines much more satisfactorily than the latter, and yields a much larger percentage of illuminating oil.

There is a lively demand for the petroleum of southern California in San Francisco and throughout the State at large. As refined by

J. A. Scott it is regarded as superior to any oil imported from the East. The oil producers at San Fernando labor under a disadvantage from which their Ventura brethren are free, notwithstanding the lighter gravity and consequent greater value of the Los Angeles product. A pipe is now being laid from Ventura to Wheeler's canyon, a distance of 27 miles, and its owners promise to pipe oil to Ventura for \$1 a barrel. From Ventura it is carried to San Francisco for 75 cents a barrel by ocean vessels. Thus the whole cost of its transportation there, from the spot where it wells out of the ground to its market in San Francisco, is \$1.75. It costs the San Fernando producer, on the other hand, just \$3 a barrel to get his oil transported to San Francisco, via the Southern Pacific railway.

The Los Angeles and Ventura oils, as refined by Mr. Scott, command about 40 cents a gallon. As there are about 45 gallons to the barrel, a barrel of this oil is worth in the San Francisco market about \$18. Mr. Morrison, an experienced oil refiner of Pennsylvania, has been sent for to take charge of the San Fernando refinery, and he will doubtless obtain results as satisfactory, in the manipulation of the crude petroleum of that section, as those achieved by Mr. Scott.

The outlook for oil production in southern California is emphatically promising. We have a better record from our oil wells to-day than the Pennsylvania wells showed at the same stage of development. Experienced Pennsylvania oil men assure us that the probability of a yield quite as prolific as that of Pennsylvania, at some time, is great. Patience, perseverance and some outlay in sinking the wells to the required depths are all that are needed. One or two failures should not dispirit prospectors. The fortune of the Pennsylvania, Ohio and West Virginia pioneers was the most variable thing in the world. One man would strike it and a man 50 feet away from him would fail. Until some wells have been sunk to a depth of 1,400 or 1,500 feet we cannot be said to have begun to prospect for oil. The kind of well-boring that has hitherto prevailed in Los Angeles and Ventura counties bears the same relation to well-boring in Pennsylvania that a claim "hogged" on the Mexican principle has to the superbly developed mines on the Comstock lode. It is much to have learned that we have in this section reliable oil wells. Their development will be certain to follow in time, just as the development of every other capability of this section has surely taken place. And we think development has fairly set in now.

California Pisciculture.

The past year has shown quite an increase in the catch of some of the varieties of fish of California. The increase in salmon has been most marked, and shows already that by artificial hatching the supply of this fish can be almost indefinitely increased. Observations during the past year have proven that this fish is to be found in California every month in the year, which is not the case elsewhere. The Fish Commissioners of this State have, so far as the means at their disposal would admit, acted with energy and good judgment.

The law making a close season between August 1st and November 1st, has been well enforced and with the result that further prosecution for violations will probably not be necessary in the future. In the carrying out of the programme of the law, the Commissioners have been materially aided by the railroad and transportation companies, who forbade their agents and employees to transport salmon out of season.

Successful Propagation of Shad.

The closed season for shad will expire in December, 1877. At that time it is believed by the Fish Commissioners that the natural increase of the fish will be so great as to prevent their extinction on this coast. As experiments have shown that young shad cannot be kept in safety for a longer time than seven days, Prof. Baird, of the United States Fish Commission, will make no attempts to send them from the Atlantic coast to Oregon. He intends, if possible, to send a full carload of young shad—about 3,000,000—during the coming season, which will be placed in the Sacramento river. With this additional number it is thought the entire Pacific coast, from San Diego northward, will be amply stocked, as from the young shad heretofore placed in the Sacramento river, adult fish have been taken at various points, from Wilmington to the Columbia river. Although the taking of shad is at present not lawful, yet numbers have been caught in nets set for other fish at various points in this State. The latest instance known to the Fish Commissioners was the taking of two adult shad in Sonoma creek last week. These fish were almost ready to spawn, and their ripe condition so early in the season shows that they can be taken here about the same time as in Alabama and Florida. During the past year the Fish Commissioners of California have placed 125,000 young shad in good condition into the Sacramento river near Tehama.

Stocking the Rivers With Salmon.

During the past year the Fish Commissioners have had hatched out and placed in the Upper Sacramento, Pitt and McCloud rivers 2,500,000 young salmon, care having been taken to distribute them in the smaller tributary streams, so as to protect these young fish from trout and other enemies. The Commissioners expect to

hatch out and put into the Sacramento and other interior rivers a similar number next year, and will continue to do so annually as long as the Legislature of California will make suitable appropriations for the purpose. From investigations made by them, the Commissioners are satisfied that the artificial hatching and introduction of the above number of young salmon yearly into the Sacramento river, in addition to the increase from natural sources, will be ample to keep up and even increase the supply of salmon beyond the consumption of our people. They believe that the business of canning salmon for export, as now practiced on the Columbia river, can, in such case, be made profitable in California. The value of salmon canned the past year on the Columbia river is estimated at about \$4,000,000, the supply being inadequate to the demand. The article of canned salmon is finding increased sale wherever introduced, and there seems practically to be almost no limit to the demands in the future. The proprietors of the canneries have already made contracts in advance for nearly 200,000 cases of the next season's catch. The limit of the supply of salmon in the Columbia river is said to have been reached, and unless artificial hatching is engaged in, that river will become as unproductive as was the case in California rivers a few years since.

Some of the parties engaged in canning salmon on the Columbia river are in favor of the State of Oregon and the United States taking some joint action in preserving and restocking that stream. They state they will assist in defraying the expense attending artificial hatching of salmon, and that a sum of \$5,000 to \$10,000 expended yearly would be ample to keep up the present supply of fish in that river. The Fish Commissioners of this State report that the 200,000 young salmon placed in the Truckee and Little Truckee rivers, Donner lake and Prosser creek have done well, the young fish having lately been seen in those waters in great numbers. Should these fish survive the perils of poison from saw dust and almost impassable dams on the Truckee river, they will find their way to Pyramid lake, and thence annually return to stock the waters from whence they came. The water of Pyramid lake is said to be somewhat salt and abounds with suitable food for salmon. During the past year the Fish Commissioners have made arrangements to exchange salmon eggs for desirable fish, natives of Japan and Hawaii. To the latter they sent 30,000 eggs, a portion of which are reported to have hatched out and doing well. From Honolulu a quantity of young fish were shipped to this port, but from lack of care died while on the voyage. These fish—the arava—are said to attain the weight of 15 pounds, resembling the salmon in looks, but tasting more like a shad, without, however, that fish's abundance of small bones. The arrangements for an exchange with Japan were made so late in the year that salmon eggs could not be sent this season. The Commissioners sent, however, by the steamer which sailed on the 3d inst., 30,000 white-fish eggs, a portion of a supply just received from Michigan. They will also send some Eastern trout eggs when received, and some eggs of the Sacramento river trout, in March next. In return the Commissioners expect to receive some mullet and carp, both being of fine eating quality. Other varieties of fish are also promised from Japan.

Importation of White-Fish Eggs.

The Commissioners have just received a shipment of 300,000 white-fish eggs in good order, from Michigan. One-half this number were sent to New Zealand by the last steamer, under arrangements made by Prof. Baird, United States Fish Commissioner. Another lot of 300,000 white-fish eggs is expected to arrive here in a few days, to be divided as above. Those retained by the Commissioners are to be hatched out at Berkeley, and afterwards to be distributed in the waters of Tahoe and Donner lakes, and Eagle lake, in Lassen county. The white fish placed some years since in Tulare lake are reported to have done well, large quantities of the fish having been seen during the past year. Of those placed in Clear lake very little is known, as very few only have been seen. As the waters of this lake are very deep, the Commissioners think the probabilities are that the fish are not likely to be taken there without systematic fishing, as is practiced in Lake Michigan, etc., which so far has not been tried in California waters.

Experiments with Eastern Trout.

The Commissioners expect to receive, about the 10th instant, 200,000 Eastern trout eggs, which are to be hatched out and placed in the public waters of this State. When hatched out notice will be given to the public through the press, so that parties who may desire to stock waters can make application and procure the young fish from the hatching house at Berkeley. The Eastern trout eggs heretofore received have been hatched out and placed in mountain streams, among others the South Yuba, North fork of the American and Prosser creek, also in Calaveras creek and other streams in Alameda, Napa and Yolo counties. These fish have grown and thrived well, a large number having spawned, thus insuring a continuous supply.

Dolly Varden Trout.

The Commissioners the past year made arrangements to secure a supply of the Dolly Varden trout eggs, under the direction of Myron Green, of the United States Fish Commission. McCloud river men were sent to the headwaters of that stream, but failed to obtain any eggs, the fish spawning in September and October, instead of February, as is the case with the Sacra-

mento trout. This difference in spawning time, however, assures the prevention of hybrids, no other trout being then ripe with milt or eggs. Efforts will be made the next season to procure a supply of eggs, with the view of distributing in other waters in the State which are supplied by melting snows, the only places where the fish will thrive. These fish were supposed to be only native to the McCloud river, but it is now known that they are to be found in almost all the snow-fed rivers of the Alaskan coast emptying near Behring straits. The name of this fish in pisciculture is *Salmo Campbellii*.

California Trout.

With the view of restocking some of the streams that have been exhausted of their natural supply of fish, the Commissioners have made arrangements to procure a quantity of eggs of the ordinary trout of this State. An arrangement has been made with Myron Green, Lower Soda Springs, Siskiyou county, by which that gentleman will collect and artificially hatch out a large quantity of trout eggs. A portion of these will be purchased by the Commissioners in March. This trout, which is called *Salmo trutta*, is highly thought of in the Atlantic States, where they are considered a shy and gamier fish than the native trout.

Graylings and Other Species.

This fish, said to be the most beautiful in American waters, will be propagated in California the coming season, the Commissioners having arranged to receive 50,000 eggs from Michigan. These, when hatched out, will be placed in some of the highest and coldest streams of the Sierras, and in time their produce will be used to stock all streams in the State which may be of suitable clearness and temperature. Of the other fish introduced into California by the Commissioners, the majority seem to have done well. The Schuylkill catfish, which were placed in the slough near Sutterville, have largely increased, and have been well distributed throughout the State. The Mississippi catfish placed in the San Joaquin river have also done well, a number weighing from three to five pounds having been taken at various times.

The black bass in Napa and Alameda creeks have largely increased in numbers, and from these creeks it is expected to stock other waters of the State.

In 1873, the Commissioners placed in San Antonio creek a number of tautog or blackfish, the only salt water variety that arrived then in good order. These fish were strong and lively, but from the time they were placed in the creek have not been heard from. They should have increased and have been found in rocky waters. The Commissioners will this season make further attempts to introduce lobsters on this coast. With this view, Livingston Stone, United States Fish Commissioner, has been making a series of experiments to keep lobsters alive for a sufficient period of time to reach California. A full carload of lobsters and salt water fish will be brought to this State during the coming season.—*Bulletin*.

Encouragement of Labor.

The Empress Eugenie has been interviewed by a newspaper man, and amongst other things tells of the various schemes she and the Emperor devised to benefit the poor laboring man. Among other things was a sort of loan society to lend money to those who were really willing to go down to work on the land, but had not money enough to enable them to subsist till the crops came in. The Empress said it was remarkable to note that hundreds applied for loans for every imaginable purpose—every one who wanted help to go down to actual labor. But she and the Emperor kept strictly to their point. No security was exacted but honor for the return of the money. The parties borrowing had to have their honor vouched for by reputable persons, and the only penalty for refusal to pay was that the voucher's words were not taken for any subsequent case. They lent out 1,000,000 francs in this way, of which all but 1,000 francs was duly returned.

This little incident proves how many people there are who will rather live by their wits than by honest labor, a hundred to one, says the Empress; and then it proves how honest real honest labor is. It proves a point we have often urged, that encouragement to earnest and honest labor is among the greatest wants of our time. We would not have "education" any less elaborate or perfect than now; but the education which encourages a whole population to live by their wits rather than by their hands, is defective, and we certainly ought to do more to encourage hard work, both in the interest of humanity in a practical sense, as well as in the interest of good morals.—*German Town Telegraph*.

BERRIES.—The Placer *Herald* says: Of all the wonders of this wondrous country, we know of nothing so remarkably wonderful as the feat of picking fresh ripe blackberries, grown on vines in the open air, at an altitude of about 3,000 feet above sea level, on Christmas day. Yet such was really done this last Christmas by Charles H. Hicks, from the vines in his garden, near Yankee Jims. As proof of the fact Mr. Hicks sent by mail, in a small box, last Monday, two sections of the vine, on each of which there were about a dozen berries in all stages of maturity; the leaves also were fresh and green. Among the lot some eight or ten of the berries were fully matured. In size they were large, in appearance fine, and in flavor would compare favorably with average summer berries.

Eureka District.

History of its Development.

A recent number of the Eureka Sentinel gave quite an interesting history of Eureka district, its growth and development, from which we copy that part relating to the mines:

The mines of Eureka district were discovered in the summer of 1864 by a prospecting party from Austin, who located mines in New York canyon and organized a mining district, with G. J. Taunehill as Recorder. Very little work was done until 1866, when Meyers, Arnold & Co. sold their claims to a New York company, who spent large sums of money in the district, but met with very poor success. The first furnace was built by Moses Wilson, in that year, and an attempt made to smelt the ores, which resulted in a total failure. The refractory ores were too much for our early miners, who knew but little of smelting, and as a consequence the district was pronounced a failure. A few indomitable spirits still stuck to it, and in 1868, Messrs. Morris, Monroe & Co. employed Mr. C. A. Stedtfeldt, of Austin, to build another furnace. It was not a success in a financial point of view, although the fact was demonstrated that the ores were rich in gold and silver, and only needed a modified process to insure a profitable return. By this time the White Pine excitement, which had carried away the most of our population, was at an end, and many miners found their way back to the district, bringing with them no capital, but stout hearts, and the little faith left them from their sad experiences on the "Pogonip." A few merchants followed in their wake, and quickly disposed of their goods—on credit—and the nucleus of a town was started. Money was scarce, lumber high, and nothing in sight but locations and drafts on the future. Notwithstanding these drawbacks, the pioneers struggled on, overcoming obstacles that would have discouraged less hardy men, and waiting for something to turn up that would give them relief. This desideratum was some process that would successfully cope with the rich, but refractory ores. In the fall of 1869, Colonel Robbins built a small furnace and demonstrated that the ores could be smelted, making a profitable run on ores from the new mines. About this time Colonel Buel leased the McCoy furnace and bonded the Buckeye, Champion, and Sentinel mines. The ores were worked successfully, they being of a character well adapted to the smelting process. This settled the fortunes of the camp and enlisted outside capital. Colonel Buel organized a company to build large smelting works. The firm, Buel, Bateman, Allen, Ingoldby and Farron, was called the Bateman Association. In the meantime Wm. Lent had purchased the mines bonded by Buel, also the Central, Roseland and Mammoth, and then effected a consolidation with the Bateman company, known henceforth as the Eureka Consolidated mining company. The ores smelted were very rich, the assays to the end of April, 1870, comprising many thousand tons, averaging \$75 gold, and \$83 silver, the ore containing about 50% lead.

The product of bullion to June 1st, 1870, was six hundred 14 u. and 10 l. s.

A good showing for the new district. Still there was a drawback. Smelting was a new method, and the furnaces built were defective in construction. From repeated experiments it was found that 30% of the silver and 40% of lead contained in the ores were lost, and the old dumps assayed as high as \$80 per ton in silver. In the fall of 1870, the Eureka company completed what was known as a modification of the Piltz furnace, and it proved a perfect success. Much of the former loss, occasioned by the unsuitable construction of the old furnaces, was entirely avoided, and the district was assured a cheaper smelting process, and a higher yield of lead and silver. There has been no improvement on these furnaces, with the exception of the dust chambers, and an automatic tapping apparatus, invented by Messrs. Keyes & Arents.

The yield of bullion for the year 1870 was \$1,500,000. There were at this time 14 furnaces built, and eight in steady operation. Substantial improvements and permanent buildings were the order of the day, and the tents and caves, or dug outs, that had heretofore been sufficient for habitations, were replaced by more civilized structures. From the discovery of the camp until 1870 our citizens were in a state of poverty. Those few who were fortunate enough to dispose of their claims went elsewhere to enjoy the proceeds, and those who stuck to the camp were living on faith and promises; but the coin commenced to flow back to Eureka, and find its way into the pockets of the producers. New industries sprang up. Charcoal was in demand and wood at a premium. The hills swarmed with men burning coal and cutting wood. The ores that had been extracted from open cuts and surface deposits became exhausted and deeper workings were necessary, which caused a demand for miners. The roads were lined between the mines and furnace, and large freight wagons and overlaid coaches filled the roads between the railroad and Eureka.

The flush times were on us, and with them came the usual influx of roughs, but, nevertheless, the town was remarkably quiet, temperate and industrious for a new mining camp. Perhaps we owe this fact to the discovery of Pioche, which place seemed to have great attraction for this undesirable class, but the fact remains that we escaped much of the disorder usually a part of life in a new mining camp. In July, 1870, the Eureka Sentinel was founded by

Messrs. McConney & Skillman, and published as a weekly. The ensuing year the outlook of the camp justified the issue of a daily, and the paper passed into the hands of Messrs. Cassidy & Elliot, and has been continued as a daily to date.

The mine par excellence of the camp was still the Eureka Consolidated, but there were several promising ones west of their ground. The Richmond, Colorado, Virginia and other locations which had been consolidated, were owned by W. C. McCoy & Co. A new consolidation was formed with Ogden, Dunne & Co., who owned smelting furnaces. This association was called the Richmond Consolidated mining company. In the fall of 1871 J. M. English negotiated a sale of this property to an English corporation, with a capital of \$1,000,000 and it passed into their hands, retaining the old title. R. A. Fisher was appointed superintendent, and extensive improvements were commenced and soon carried to completion. Four additional furnaces were built, and land was donated by Major McCoy to the company for this purpose. The Jackson, Buttercup, Phoenix, Bullwhacker, General Lee, Dunderberg and Wide West were swelling the stream of bullion and contributing to the general prosperity. It would take too much time and space to follow the mines in detail, noting the various changes up to the present time, but all these properties are still yielding ores, and are worked under various names. The Eureka Consolidated and Richmond remain the foremost mines in the district. They have both attained a depth of 1,000 feet, and the body of ore in the Richmond is of vast proportions and increased value, and rivals the famed Comstock. The bullion yield increased yearly and culminated in 1875, when we shipped \$6,000,000. The yield fell off in 1876, but the decrease was owing to the depreciation in silver and other causes, but even then the shipments amounted to over \$4,000,000.

We have sketched what may be termed the opening chapter in our history. From a few pioneers the population had increased to 4,000 souls. The canvas and log houses were being rapidly replaced by brick and stone structures. Bullion flowed in a steady stream from our furnaces, and the evidence of permanent wealth and stability was found on every mountain side within the range of vision, and one would suppose that with all this testimony in our favor there would be few doubters. There certainly were none among those who had examined our mineral resources. It is true that none of the mines had attained any great depth. To offset this, was the known fact that all over the globe mines that carry base metal ores have proved to be the most permanent, but San Francisco shouted limestone, and the Comstock echoed back the cry, accompanied with the babble of the would-be scientists about true fissure veins. In fact, it seemed to have become an axiom that there could be no permanent bodies of ore that did not fulfill all the conditions of the Comstock lode. The unfortunate result of operations in White Pine was cited to support this theory, and timid capitalists shook their heads and buttoned up their pockets when Eureka was mentioned, while the few sanguine ones reaped a rich reward for their investments. We well remember before the bonanzas were found in the Crown Point and Belcher, and the prospects were not very bright in Virginia City, that the same dismal predictions were made of her future. A true fissure vein was there all the same, and theories were as tenable before as after its discovery, but it did not inspire capital with confidence, and the papers of that city tell to-day how it was that the indomitable perseverance of one man redeemed it from ruin while capital stood aloof and waited for the result. Turning from the modest outlook of 1870 to the firm basis of 1877, we congratulate our townsmen on the overwhelming evidences of our present stability and future prospects. The fact is conclusively established that our mines have yielded and are still yielding large quantities of gold and silver. They have been worked to a depth that proves all theories antagonistic to their permanence, false in fact and false in conjecture. The problem of successful reduction has been overcome, and the returns by smelting are as sure as any other process, and the only one applicable to our ores.

BANCROFT'S.

A. L. Bancroft & Co. keep on hand a large stock of American and European Books, Suitable for

CIVIL ENGINEERS,

FARMERS,

MACHINISTS,

And Industrial Classes generally, and supply them, post free, at published prices; for particulars of which, see catalogues, which will be forwarded on application.

A. L. BANCROFT & CO.,

721 Market Street, S. F.

Banking.

KOUNTZE BROTHERS, BANKERS.

12 WALL STREET, NEW YORK.

Allow interest at the rate of Four per cent. upon daily balances of Gold and Currency.

Receive consignments of Gold, Silver and Lead Bullion, and make Cash advances thereon.

Invite Correspondence from Bankers, Mining Companies, Merchants and Smelting Works.

French Savings and Loan Society,

411 Bush Street, above Kearny.

SAN FRANCISCO.

BARTLING & KIMBALL,

BOOKBINDERS,

Paper Rulers & Blank Book Manufacturers.

505 Clay Street, (southwest corner Sansone), SAN FRANCISCO.

Machinery.

The Gardner Automatic Governor.

MORE THAN TEN THOUSAND NOW IN USE. EVERY ONE WARRANTED.

SEND FOR DESCRIPTIVE CIRCULAR AND PRICE LIST.

When all others fail, buy a "Gardner." We have all sizes of these celebrated Steam Governors on hand at all times.

BERRY & PLACE

Selling Agents for the Pacific States, Cor. Market & Fremont Sts., S. F.

THE O'HARRA

CHLORIDIZING FURNACE

Guaranteed to Chloridize from 85 to 95 per cent. of any gold or silver ores that are not more profitable for smelting. Will also desulphurize ores and put them in proper shape for working in cupola furnaces.

Cost of Roasting and Chloridizing by this Process:

Two cords of wood at \$0.50.....	\$12.00
Two firemen at \$4.....	8.00
1,500 lbs of salt at 14c.....	22.50
Wear of shoes and power.....	1.50

Cost for 15 tons.....	\$44.00
Cost for one ton.....	2.93

In a furnace of three or four times this capacity the cost is decreased by 20 per cent.

The furnace is now working successfully at the Poe Consolidated Co.'s mines, in the Peavine District. For further information, apply to

D. J. O'HARRA,

Reno, Nevada.

LOOK

The Great Western Scroll Saw Co.'s new and improved \$5.00 Foot and Steam Power Scroll and Bracket Saw is the best one yet invented. With it men and boys are making from \$3 to \$10 per day. We will send you a Machine, six Saws, 15 Patterns and Address,

GREAT WESTERN SCROLL SAW CO.,

Leavenworth, Kansas.

DEETK N ROASTING FURNACE.

The CHEAPEST and MOST EFFICIENT furnace for GOLD, SILVER and COPPER ORES. Capacity of furnace from six to fifty tons per day.

Apply to

G. T. DEETKEN, Consulting Metallurgist,

Grass Valley, Cal.

PICKERING ENGINE GOVERNOR.

Vallejo Foundry, October 17th, 1876.

Messrs. NEYLAN & YOUNG, San Francisco.

Agents "Pickering Governors."

Gents:—The 10 two-inch Improved Speed Adjusting Governors I bought of you this year for my patent Straw

Burning Threshing Engines give splendid satisfaction. They far surpass for regularity of speed any Governor that I have ever seen, and I have seen all the best kinds. I have seen the main belt fly off the pulley several times this season while threshing, and the engineer did not discover it, so perfectly was the speed maintained, until he was told of it; this I consider something wonderful. I consider the Governor absolutely perfect, so far as speed is concerned. I bought and put on to one of my engines a Shive Governor, to see which was the best, and after one season's trial I have no hesitation in saying they are as far superior to the Shive or any other Governor that I have seen or used.

as the Shive Governor is to the old Butterfly Valve Governor. I wish you would send me the lowest price that you can furnish 25 Governors for next season's engines.

Yours respectfully,

I. L. HEALD.

The Ingersoll Rock Drill

Is Extensively Used in the East and

TAKES THE PLACE OF ALL OTHERS,

Wherever introduced, because it can be run with less power, labor and repairs, and do more work than any other drill in the market. It has but few parts, is easily handled, being light, and has AUTOMATIC FEED, which saves labor. WE ASK FOR TRIAL AGAINST ANY COMPETITOR. For particular information regarding Drills or Air Compressors, send for circular to

J. B. REYNOLDS,

426 California Street

STEAM ENGINES, SAWMILLS, SHAFTING, GEARING AND MINING MACHINERY.

Send for our Illustrated catalogue.

The Leading Optical Depot of the Pacific Coast.

C. MULLER,

Wholesale and Retail Optician,

IMPORTER OF OPTICAL GOODS,

No. 135 Montgomery Street, near Bush, SAN FRANCISCO.

Sportsmen, Tourists and Pleasure Seekers are invited to examine our celebrated Tourists' Glasses, which, for power and durability, are unequalled.

SPECTACLES—Their adaptation to the various conditions of sight has been my specialty for upwards of 30 years. Send for Muller's Pebble Spectacles. Directions and Price List Mailed Free. Orders by mail receive prompt attention. Goods forwarded per Wells, Fargo & Co., C. O. D. (subject to approval).

Those contemplating making Holiday Presents, take notice.

C. MULLER, Optician,

135 Montgomery Street, San Francisco.

THIS NEW

ELASTIC TRUSS

Hass Pad differing from all others, is cup-shaped, with Self-Adjusting Ball in center, adapts itself to all positions of the body, while the ball in the cup presses back the intestines just as a person would with the hand. With light pressure the Hernia is held securely day and night, and a radical cure certain. It is easy, durable and cheap. Sent by mail. Circulars free.

EGGLESTON TRUSS CO., Marshall, Mich.

Any person receiving this paper after giving an order to stop it, may know that such order has failed to reach us, or that the paper is continued inadvertently, and they are earnestly requested to send written notice direct to us. We aim to stop the paper promptly when it is ordered discontinued.

Continued from page 41.

there yet, and extensive tunnel claims are also being worked. The mining outlook of the county is considered as extremely encouraging. In the upper part of the county several new enterprises are being carried on. The Railroad canal will be extended to Mosquito gulch this summer, taking the ditch through ten miles of mining country hitherto unsupplied with water facilities.

In Butte county the Chinese continue to work the lava beds below Oroville. About \$20,000 per month is taken from these mines. Some of them have paid well and others not.

The Siskiyou and Humboldt county mines are principally quartz, of which the Black Bear is the most profitable. Some placer mines are worked in bars and beaches, but mining is not carried on in a very extensive manner.

In Mono county, where mining was for so long a time a failure, better work is now being done, and capitalists have of late turned their attention that way, so that we may soon expect to hear of an improvement. In several cases this year good results have been made and the county will probably redeem itself before long.

Inyo county has probably made greater strides this year than any other of the mining centers of the State, although much remains to be done there yet. The old Cerro Gordo base bullion district is rather under a cloud, and Panamint has not answered the expectations hoped for, but the Darwin, Lookout and Lee districts are coming to the front. There are now in the county three mills at Independence, two furnaces at Cerro Gordo, two furnaces of the Modoc mine at Lookout, and the New Coso furnace at Darwin. The 30-ton furnace at the Hidalgo mine is about starting up, and a 10-stamp mill for the Minetta Belle mine at Lookout. The two furnaces of the Defiance are also at work. A number of the mines are doing well, the Modoc particularly, which paid its first dividend this month. The Union Consolidated, at Cerro Gordo, yielded 1,325 tons of lead last year, reducing 9,950 tons of ore at a cost of \$137,826.

Mendocino county has come into the rank of mining counties this year, by the discovery of the Calpella placers. There are about 1,000 acres of land available for mining purposes. A ditch is now being built to work the ground by hydraulic system.

San Benito county mines, mainly quicksilver, give promise of better results before long. These mines are near the summit of the mountains dividing San Benito from Fresno county, at a level of 3,350 feet above the valley level. The Staton mines, worked previously for quicksilver, are now worked mainly for antimony, the furnaces now being run on this ore. The deposits of antimony, of which 50 at least are uncovered, show large bodies of fine metal. They have large quantities of both cinabar and antimony ore, and have abundant wood and water facilities, with good means of transportation. The Consolidated Wonder group, on the north of the Staton mines, comprise some 20 promising discoveries. A furnace will soon be constructed.

In addition to the products heretofore named, this State also produces lead, copper, borax, soda, manganese, salt, cement, gypsum, antimony, plumbago, asbestos, nickel, kaolin, fire-clay and other mineral products. The past year has seen a very great increase in oil production, the petroleum mines in the lower country having had the aid of capital to develop them. The oil interests of the southern part of the State are now quite extensive. New mines are being opened, refineries erected and a large section of country prospected, and we may expect a great increase in this business in the coming year.

Quicksilver.

Although within the past few years the quicksilver mining interests of California have been very greatly developed by the discovery and opening of new mines, erection of furnaces, etc., in 1876 quicksilver mining has not been very profitable. In fact, many small mines have had to close down temporarily. Many which started in with brilliant futures when quicksilver was selling for \$1.65 per pound, stopped working when it dropped to 50 and 60 cents per pound, as it ruled of late. It is, of course, much better for the gold and silver miners to get their quicksilver so cheap, but it has had a bad effect on many quicksilver mining companies. This State now produces fully one-half the product of the world in this article. The total receipts of quicksilver in San Francisco in 1876 were 63,928 flasks, against 50,246 flasks in 1875—an increase of 13,682 flasks. Until this year the lowest average price since 1870 has been 80 cents per pound, and prices this year have been by no means satisfactory to the quicksilver miners. The total value of the exports of this article for the year is set down as \$1,638,859. A very large proportion is of course exported. 40,992 flasks having gone by sea and 7,963 flasks overland. The mines of this metal extend almost the whole length of the Coast range, and a number of new ones have been discovered this year. We append the figures of production of the principal mines:

New Almaden, Santa Clara county.....	Flasks.
New Idria.....	29,651
St. John and Vallejo mines, Solano county.....	7,272
California.....	2,085
Sulphur Banks, Lake county.....	1,184

Altosna.....	2,000

Coal.

The fact that the Pacific coast import of coal amounts annually to from 250,000 to 350,000 tons, would lead one to suppose that we produced no coal of any amount. This is by no means the case, as large deposits exist in various parts of the coast and are being worked. The great Rocky mountain coal field, extending through Montana, Idaho, Wyoming, Utah and Colorado, and covering a large area, has scarcely been touched. The Coast range deposits, such as the deposits of Mount Diablo, Sacramento valley, the Coos bay, Oregon, and Seattle, Washington Territory, mines, are more generally worked. Most of our coal is "soft," and not of a first-class character, lignite being the most abundant. The Seattle coal is the nearest approach to anthracite known to the coast. The past year has not by any means been a successful one for the coal interests of the coast. A large number of vessels, attracted here by the wheat crop, have come from Australia or England with cargoes of coal and have brought it almost as ballast, for so cheap a rate as to depress our local coal interests. This has made little difference to the consumer, however, as to price, although the dealers have made money by it, while our local coal industries have been injured. Contra Costa county has been the largest coal-producing section of California, but, as stated above, the industry has not been profitable in 1876. The Union mine, at Summersville, one of the largest mines, has suspended work indefinitely. The coal has been worked out to such an extent that extra pumping apparatus is necessary, and the expense is not warranted by the low price and small demand. The Pittsburg has been idle for several weeks, and Central has not shipped any coal this season. The Antioch Ledger gives as follows the amount of coal that has been shipped from the Central, Union, Pittsburg, Eureka, Black Diamond, Peacock and Independent, since 1860:

	Tons.	Tons.
1861.....	6,320,1869	148,722
1862.....	2,342,1870	120,760
1863.....	43,198,1871	133,485
1864.....	37,468,1872	163,322
1865.....	60,530,1873	170,000
1866.....	80,024,1874	205,256
1867.....	109,490,1875	142,808
1868.....	133,839	
Total for 15 years.....		1,591,914

In addition to this, the Corcoran and Empire mines have shipped several thousand tons, and large sums of money have been expended in opening the Teutonia and Brentwood mines, which will doubtless be successfully worked in the near future. No figures are given for the year 1876. The coal from this region is principally used for boiler coal, and is not so well adapted for domestic purposes as the imported varieties.

The Lincoln, Ione and Livermore coal mines, which are now producing, give promise of an excellent future, and bid fair to become important coal centers. In Sonoma county several veins of coal have been found, none of which have as yet been prospected sufficiently to prove their value. In addition to this, coal was found last year in Santa Cruz, Monterey, Santa Barbara and Los Angeles counties. In all these places prospecting for coal is being actively prosecuted in various directions, while the deposits already found are being tested. As yet, however, the developments are not such as to warrant any prediction of their value, although there is no reason why all of them should not prove good coal mines. The fact that these coal deposits seem to be scattered over so large an area is an encouraging one, as in all directions population is increasing and towns building up, where coal is needed. It argues well also for new discoveries not yet made and the success of a few companies will set others on the track.

Iron.

The Pacific coast uses annually about 50,000 tons of iron, a large proportion of which could be produced by its iron mines were sufficient attention paid to the deposits. Capitalists have, however, not yet entered this field of industry, although indications are now apparent that the deposits will not be allowed to lie idle much longer. Oregon iron has for some time been known as first-class, but for some reason the company which used to work the deposits at Oswego have been obliged to suspend operations. The Oregon deposits extend from Portland on the Willamette to St. Helens on the Columbia, but little has been utilized. In California it is found all over the State from one end to the other. The main difficulty in the way of the development of this industry is the lack of proper fuel for the furnaces. Several iron mines have been located lately by different companies, some of which will be worked this year. The Eureka company, recently organized, is to work a hematite mine in El Dorado county, about two miles from Placerville. The ore is inexhaustible, and said to assay from 65 to 80 per cent. iron. There is near by plenty of wood for charcoal and a deposit of limestone, which can be used for a flux. As yet, however, there is not a single iron furnace in blast in the State of California, notwithstanding the consumption of iron and the existence of large and valuable deposits. The precious metals attract most

attention from our miners and capitalists, few of whom are familiar with iron mining.

Nevada.

The State of Nevada is now the greatest bullion producing region in the world. The famous Comstock lode of course produces most of it, yet there are many other productive districts which yield amounts to swell the gross product very materially. We have not space here to mention individual mines outside of very prominent ones, nor to give even a brief review of operations in the numerous districts which are scattered all over the State. The figures of production show for themselves the prosperity of the industry. The following mines have produced in 1876 the figures set opposite the names. Of course there are hundreds of others, the returns from which are not obtainable, yet the brief list which we have made up makes a good showing:

Consolidated Virginia, Comstock.....	\$16,657,649 47
California.....	13,386,050 39
Belcher.....	2,820,590 36
Opbir.....	2,340,848 70
Crown Point.....	904,339 80
Chollar-Potosi.....	457,248 25
Con. Imperial.....	138,238 66
Imperial.....	24,657 34
Overman.....	55,990 07
Bullion.....	45,000 00
Eureka Con., Eureka District.....	602,825 55
Richmond Con. ".....	2,167,202 25
K. K. Con. ".....	200,000 00
American Flag, Pioche.....	48,009 97
Raymond & E. ".....	578,242 61
Leopard, Cornucopia District.....	480,908 86
Tybo Con., Tybo District.....	623,274 47
Manhattan, Lander county.....	1,240,000 00
Paymaster, Ward District.....	230,000 00
Northern Belle, Esmeralda.....	1,517,685 30
Jefferson, Nye County.....	102,383 89

Of course the Comstock continues to be the center of attraction, as it always will. In the vicinity of that lode there are a number of what are termed outside mines, which have this year received attention and are being worked. Eureka district continues to flourish, as the figures we give elsewhere of the product of the mines prove. The Richmond and Eureka Consolidated are the most prominent and the largest producers. The Manhattan mine in the Reese River country produced \$1,229,679 this year. The mines themselves have greatly improved and are daily showing a continued improvement in size of veins, extent of chimneys and quality of ore. Eastern Nevada has looked up of late and most of the districts now give better promise than ever before. We have given in the Press all the current news from these localities weekly, so it is not necessary to refer to them more in detail here.

Mines of the State of Nevada belong principally to citizens of this city, and most of the capital employed comes direct from here, so that our community is as much interested in the developments there as here. A good many of the old districts are coming to life again as prospectors prove the worth of mines in their boundaries. Again, new districts are discovered and settled up, so that the mining developments of the State are on the up grade. The past year has been a comparatively dull one, however, the heavy discount on silver having a disastrous effect in some instances, and there are probably more miners in some of the districts than there is room for. Still, with these drawbacks, the State makes a splendid showing and one to be proud of.

The Suro tunnel, intended to drain and ventilate the Comstock lode, is more vigorously prosecuted than ever, and it may be safely counted that they make about ten feet per day, by the aid of Burleigh drills and fine machinery. The cost of the work so far has been over two millions and a half, and it is expected to strike the lode within the next twelve months. As yet no bonanzas have been struck, although some fair milling ore has been crossed. As they near the lode, however, the chances are expected to increase for finding blind ledges and they may strike something yet. It remains to be seen, however, whether all that is claimed for the tunnel will be realized when it reaches the lode. It was a stupendous undertaking, and has been carried forward energetically, so that the projectors are deserving of the reward they expect.

Utah.

In Utah Territory active mining has not been carried on to any great extent for more than five or six years, and although the bullion production is quite respectable, the Territory has labored under many disadvantages. The people who went there early expected to get rich in a day, and in failing to do so by the mines themselves, in several famous instances tried to get rid of the mines at fabulous prices. Values were inflated and capital invested was not returned in any proportion to its investment. At one time it was thought that the silver-lead mines of Utah would equal if not exceed the silver mines of Nevada and the gold of California. Eastern capital flowed in abundantly for a time, but reverses checked it, and the Territory did not "pan out" as was hoped for. An adventurous class of men seemed to have hold of the mines, and instead of working them legitimately they took advantage of the ignorance or confidence of investors and brought Utah mines into bad repute. The Territory has probably learned by experience the fallacy of this course of treatment and passed through the unhealthy period of its existence. The progress in mineral development for the past year has been encouraging. Quite a number of new mines have been found in the various districts which show rich and apparently permanent leads or deposits. The mines are none of them deep enough, however, to give confidence to investors. Capital is necessary for machinery to test the mines.

But capital, though once abundant, is now scarce. Another difficulty is the lack of available means of transportation for ores to bring them to a market. Coal or charcoal for the smelting furnaces is greatly needed. In 1875 about 1,400 tons of coke were imported from Pennsylvania for the use of the smelting works and about 60,000 tons of coal from the mines along the Union Pacific railroad. It is represented that the San Pete coal fields, about 100 miles southeast of Salt Lake City, would produce all that is required if a railroad were provided to transport the fuel.

As stated previously, most of the mines produce silver-lead ores, and naturally the smelting operations are very important in connection with them. A great many smelters have been started and are in operation, but still many others have failed, showing that either ignorance of the business or poverty of the ores was the cause. The business of smelting, however, is becoming better understood with practice, and low grade ores are reduced to base bullion much more successfully than formerly. Several new smelters were built last year and a number of old ones started up again. The Salt Lake Tribune gives a list of the smelters and says that in Salt Lake county there are eleven smelters, eight of which are in operation, and are turning out on an average about 70 tons of base bullion daily of about \$14,000 value. The bullion shipped from the Territory according to the tonnage report of the Utah Central Railroad for the year 1876 amounts to 20,039 tons, while reports from the smelters show as follows:

Mine.	Tons.	Amount.
Flagstaff.....	2,000 @ \$200	\$400,000
Davenport.....	2,000	400,000
Germania.....	1,700	340,000
Sheridan Hill.....	1,740	348,000
Galena.....	2,330	470,000
Saturn.....	1,660	332,000
Wasatch.....	100	20,000
Morgan.....	350	70,000
Pascoe.....	1,900	380,000
Chicago.....	2,517	503,400
Waterman.....	2,100	420,000
Longmaid.....	1,700	340,000
Total.....	20,047	\$4,009,400

The Tribune says: The product for 1875 was 16,330 tons, estimated at \$250 per ton, of a total value of \$4,082,500. Compared with the product of the past year, it is seen we have produced twenty per cent. more bullion, but lead and silver have depreciated in the market twenty per cent., so that while we have produced more in bulk there has been no increase in value.

Of the bullion produced during the year that from Tooele amounts to 6,327 tons, and that from Salt Lake 13,720 tons.

There are eighty-seven mining districts in Utah; the one attracting the most attention at present is probably Leeds district, in Washington county. Although known for some time, it has only now come to favorable notice. The formation is sandstone, which has had the effect of keeping away capital, as there is little experience with mines in this formation. San Francisco capitalists have gone in, however, and purchased several mines under the name of the Leeds mining company. The town of Silver Reef has been laid out, and has a population of about 1,000. A mill is in course of construction by the above named company; one custom mill is completed and two are promised. The miners are principally from Ely district, Nevada, many of the people of Pioche having gone to Leeds of late. A large influx is expected in the Spring. Up to November 1st there were only 25 men in the district, yet some fourteen or fifteen mines have produced since that date the sum of \$205,190—a good showing for a new district in so short a time.

Montana.

As a gold producing country Montana stands next in order to California, and although the production has fallen off of late years on account of mines being worked out, new discoveries are being made and new ground is opened. Some of its mountainous country is yet imperfectly prospected, such as the southeastern portions on the tributaries of the Big Horn, Powder and Tongue rivers. In all there are said to be about five hundred gold-bearing gulches in Montana, varying from half a mile to twenty miles in length, and in nearly all of them gold mining is carried on during six or seven months in the year. The length of ditches bringing water to the mines will aggregate six hundred miles. There are twenty mills in Lewis and Clark county. At Silver Star, Summit, Meadow Creek and Sterling, in Madison county, Radersburg and Crow Creek, in Jefferson, and several others mills are at work on quartz with variable results. It is only of late that much attention has been turned to silver mining in Montana, but now several mills and furnaces are at work on ore. There is a rich belt of argentiferous lodes in Ten Mile, Prickly Pear and Boulder Creek. This same belt has an outcrop at Butte, Deer Lodge county, and still further at Vipond and Bryant districts, in Beaverhead county. There are several mills at Butte, and the luviation process has also been recently introduced. The Territory is inadequately supplied with reduction works and large quantities of ores are shipped away. A large amount of copper is also mined and the ore shipped to Baltimore. Our correspondent who is now traveling in the Territory, has in late numbers given a series of interesting letters on Montana mining matters which give more details than we are able to refer to here. The great need of the territory is capital, for they have plenty of good mines scattered over a large area. They need men of

means to start them up, however, which cannot be done by mere working miners.

Arizona.

The main industry of Arizona is mining, and she has within her borders fine mines of gold, silver, copper, lead, iron and coal. Her mines have not been developed to any extent, however, for various reasons. Now, however, that the Southern Pacific railroad will soon reach her borders, they all hope and reasonably expect for an awakening of the mining interests. Judging from the quality of the ore shipped from there here occasionally she has the richest ore of any section of the Union. Several new districts have been opened this year, prominent among which is Globe, which we recently described in an extended article. The Territory is in need of reduction works and means of transportation, and our capitalists will find a rich harvest if they turn their attention that way. Arizona will before long be one of the principal if not the principal bullion producing regions of the United States. Only capital is necessary to develop the resources, as the mines are good and ore rich. We look for greatly increased returns from there this year in view of better means of transportation and more facilities for mining. The following figures show the product of some of the principal Arizona mines:

McCracken mine.....	\$ 78,687 21
Hondoo, Globe District.....	50,000 00
Silver King.....	140,000 00
Hackberry, Mineral Park, Mohave County.....	100,000 00
Keystone.....	35,000 00
Lone Star.....	30,000 00
Metallic Accident.....	10,000 00

Idaho.

In Idaho mining operations continue pretty much as usual. The local papers state that the Basin has done better this year than for the past five years, placing the product at \$1,000,000 and estimating the expected product of 1877 at double that amount. The mines of the Territory have been under a cloud here for some time. The quartz mines at Owyhee, which we have listed on our stock board, have been so badly managed for several years that the name of an Idaho mine was always coupled with that disagreeable word "assessment." This was by no means the fault of the mines, but of the managers, and considerable trouble was experienced there last year. The miners were not paid, although assessments were levied, and they had pretty hard times over there. The prospect has partially cleared up, however, and it is to be hoped that this year the miners of Idaho will have a better show. The miners certainly seem energetic and persevering enough, and the mines are good enough, but for the reason stated they are not in good repute here.

Oregon, Washington Territory and Colorado.

We have little new to report from Oregon. Some new ground has been opened and ditches built, but the industry remains about stationary there. Washington Territory, although producing some gold, has its richest mineral product in coal, of which it supplies this coast with large quantities. Colorado holds its own in mining matters, but its mining developments have less of interest for us here than they have for Eastern people. There is little, if any, California capital in Colorado, most of what they have invested coming from the East or Europe. The mining ground seems to cover nearly the whole State, but the gross production is less than one would suppose it to be, considering the number of mines. Many localities there, however, as elsewhere, are suffering for want of the aid of capital.

PATENTS AND INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

FOR WEEK ENDING JANUARY 20, 1877.

ORE ROASTING FURNACE.—William K. Alderley, Colusa, Cal.

FOR WEEK ENDING JANUARY 20th, 1877.

PUMP VALVES.—Garrett D. Hopper and William H. Laufkotter, Sacramento, Cal.

Land Commissioners.—Different Classes of Public Lands; How Lands may be Acquired; Fees of Land Office at Location; Agricultural College; Scrip; Pre-emption; Extending the Homestead Privilege; But One Homestead Allowed; Proof of Actual Settlement Necessary; Adjoining Farm Homesteads; Lands for Soldiers and Sailors; Lands for Indians; Fees of Land Office and Commissioners; Laws to Promote Timber Culture; Concerning Appeals; Returns of the Register and Receiver; Concerning Mining Claims; Second Pre-emption Benefit.

Abstract From the U. S. Statutes.—The Law Concerning Pre-emption; Concerning Homesteads; Amendment of Law Concerning Timber; Miscellaneous Provisions; Additional Surveys of Land for Pre-emption; List of California Post Offices.

Published and sold by DEWEY & CO., S. F.

To Mining Secretaries.

An amendment to Section 336 of the California Code, taking effect July 1st, 1874, provides that in addition to the regular publication, daily or weekly, of the assessment and sale notices as heretofore,

PERSONAL NOTICE

Must be served as provided in the following quotation from the law:

"The notice must be personally served upon each stockholder, or in lieu of personal service, must be sent through the mail, addressed to each stockholder at his place of residence, if known, and if not known, at the place where the principal office of the Corporation is situated."

The above refers to the ASSESSMENT NOTICE only. Advertisers in the MINING AND SCIENTIFIC PRESS will be furnished with copies of assessment notices printed on slips suitable for serving personal notice under this law at short notice.

DEWEY & CO., Publishers.

Mining and Other Companies.

Aetna Tunnel Company.—Location of principal place of business, San Francisco, California. Location of works, Alta City, Salt Lake County, Territory of Utah.

Notice is hereby given that at a meeting of the Board of Directors, held on the second day of January, A. D., 1877, an assessment (No. 1), of three cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary, at the office of the company, Room 6, No. 420 California Street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on Monday, the 26th day of February, 1877, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 19th day of March, 1877, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

JAMES M. HAVEN, Secretary.
Office, Room 6, No. 420 California Street, San Francisco, California.

Great Bay Gravel Range Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Placer County, State of California.

Notice is hereby given that at a meeting of the Directors, held on the 22d day of December, 1876, an assessment (No. 7), of Fifty Cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin to the Secretary at the office of the company, Room 33 Merchants' Exchange, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid, on Monday, the 26th day of January, 1877, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Wednesday, the 14th day of February, 1877, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

JAMES M. HAVEN, Secretary.
San Francisco, Cal.

Howland Tunnel Company.—Location of principal place of business, San Francisco, California. Location of works, Alta City, Salt Lake County, Territory of Utah.

Notice is hereby given, that at a meeting of the Board of Directors, held on the second day of January, A. D., 1877, an assessment (No. 1), of three cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary, at the office of the company, Room 6, No. 420 California Street, San Francisco, Cal.

Any stock upon which the assessment shall remain unpaid on Monday, the 26th day of February, 1877, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 19th day of March, 1877, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

JAMES M. HAVEN, Secretary.
Office, Room 6, No. 420 California Street, San Francisco, California.

Josephine Gravel Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Brushy Canyon, Placer County, California.

Notice.—There are delinquent upon the following described stock, on account of assessment (No. 2), levied on the 6th day of December, 1876, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. shares.	Amount.
Boyd, Jno F, Trustee.....	10	1500	150 00
Boyd, Jno F, Trustee.....	11	500	50 00
Boyd, Jno F, Trustee.....	13	100	10 00
Duncan, Adam.....	21	200	20 00
Duncan, Adam.....	22	200	20 00
Duncan, Adam.....	23	100	10 00
Duncan, Adam.....	20	200	20 00
Ingersoll, J. E.....	27	400	40 00
Kates, J. F.....	24	200	20 00
Kay, Joel.....	18	50	5 00
Kay, Joel.....	32	1000	100 00
Kay, Joel.....	33	1000	100 00
Kay, Joel.....	35	500	50 00
Small, Wm, Trustee.....	31	500	50 00

Walsh, Wm.....	63	100	10 00
Walsh, Wm.....	65	25	2 50
Walsh, Wm.....	66	25	2 50

And in accordance with law and an order of the Board of Directors, made on the 6th day of December, 1876, so many shares of each parcel of said stock as may be necessary, will be sold at public auction at the office of the company, No. 531 California Street, San Francisco, on the 25th day of January, 1877, at the hour of 2 o'clock, P. M., of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

WM. SMALL, Secretary.
Office, Room 1, No. 531 California Street, San Francisco, California.

Mariposa Land and Mining Company of California.

Location of principal place of business, San Francisco, California. Location of works, Mariposa County, Cal.

Notice is hereby given, that at a meeting of the Board of Directors, held on the sixteenth day of January, 1877, an assessment (No. 9), of one dollar per share was levied upon the capital stock of the corporation, payable immediately in United States currency, to the Secretary, at the office of the company, Room 33, Nevada Block, No. 300 Montgomery Street, San Francisco, California, or to the Assistant Secretary, at the office, No. 9 Nassau Street, New York, N. Y.

Any stock upon which this assessment shall remain unpaid on the seventeenth day of February, 1877, will be delinquent, and advertised for sale at public auction, and unless payment is made before will be sold on Monday, the nineteenth day of March, 1877, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

LEANDER LEAVITT, Secretary.
Office, Room 33, Nevada Block, No. 300 Montgomery Street, San Francisco, California.

Annual Meeting of the Sierra Iron Co.

The Annual Meeting of the Stockholders of the Sierra Iron Company will be held on Saturday, the 27th day of January, A. D., 1877, at 2 o'clock P. M., at the office of the company, No. 9, Halleck Block, 318 Sansome Street, San Francisco, to elect Trustees.

CALVIN T. FAY, Secretary.
San Francisco, January 13th, 1877.

Silver Sprout Mining Company.—Principal place of business, San Francisco, State of California.

Location of works, Kearsarge Mining District, Inyo County, State of California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the nineteenth day of December, 1876, an assessment of twenty cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary at the office of the company in San Francisco.

Any stock upon which this assessment shall remain unpaid on the fifteenth day of February, 1877, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Saturday, the fourteenth day of April, 1877, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

Office, Room 20, No. 328 Montgomery Street, San Francisco, Cal.

Taylor Mill and Mining Company.—Principal place of business, City and County of San Francisco, State of California.

Location of works, Garden Valley Mining District, El Dorado County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 27th day of December, 1876, an assessment of Twenty Cents per share was levied upon the capital stock of the company, payable immediately in United States gold and silver coin, to the Secretary at his office, No. 607 Montgomery Street, in the City and County of San Francisco.

Any stock upon which this assessment shall remain unpaid on the 28th day of January, 1877, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Friday, the 23d day of February, 1877, to pay the delinquent assessment, together with costs of advertising and expenses of sale.</

EXCLUSIVE IMPORTERS FOR THE PACIFIC COAST.

PATENTED
CAST STEEL SHOES AND DIES.

Guaranteed Cheaper than the Best Iron.

IMPORTANT NOTICE.
Reduction in Price from 16 Cents to 12 Cents Per Pound.

Owing to our largely increased business, the present low price of iron from which our Steel is manufactured, and the improved facilities for casting and forging, we take great pleasure in announcing that from and after this date we will supply our IMPROVED CAST AND FORGED STEEL SHOES AND DIES FOR QUARTZ MILLS at twelve cents per pound, delivered at San Francisco or Sacramento, instead of sixteen cents, as heretofore.

We also furnish Steel Plates for Blake and other Ore Crushers, Steel Cut Gearing, etc., for Mills and Hoisting Works, Steel Pan Shoes, Battery Cams and Tappets, etc., etc.

Address all orders, with dimensions or drawings, to

CAST STEEL SHOE & DIE CO.,

59 Nevada Block, S. F.

THE ASBESTOS PATENT FIBER COMPANY,

TWO MEDALS OF HONOR.

Of Philadelphia, offer for sale through their agent in San Francisco,

Asbestos Steam Packing, Asbestos Boards and Asbestos Steam Joints,

All manufactured from the pure utilized Asbestos Patent Fiber, and under patents granted to J. S. Rosenthal. The packing is in all sizes from one-quarter to three inches in diameter, round, and free from all grit or mineral matter. The non-utilized or crude Asbestos, manufactured by some parties into packing, is impure and gritty, liable to injure the piston rod and should not be used. The packing made under the Rosenthal patents is of pure utilized Asbestos fiber, and a very superior article and entirely different from the so-called Asbestos packing heretofore offered for sale. It is compact in form, will not fuzz or disintegrate, and will wear much longer than any other kind of packing. The indestructible, expanding, contracting and lubricating qualities of Asbestos are now universally recognized, and packing made from it is peculiarly adapted for steam engines and pumps.

ASBESTOS PATENT FIBER BOARD.

This is the champion non-conductor, to prevent radiation of heat and condensation of steam, as covering for marine, stationary, or locomotive boilers and pipes, and for lining wood-work, where exposed to great heat. It is light, flexible, is not disturbed by vibration, and will not char or crumble. The sheets are 30 by 44 inches, of any desired thickness, and are easily applied.

ASBESTOS PATENT FIBER STEAM JOINTS.

Indestructible by fire or water, expands and contracts in a desirable manner, adjusts itself to any rough point, is cheaper than rubber, and in all respects a superior article. PURE ASBESTOS FIBER for packing steam governors and other purposes. All these goods are extensively used in the Atlantic States and give general satisfaction.

PHILIP HINKLE,

Also, For Sale by

DUNHAM, CARRIGAN & CO.,

107 & 111 Front Street.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS OFFICE, S. F.

BY GUIDO KUSTEL,
MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their respective Metals without Quicksilver. 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty.

Price, \$2.50 coin, or \$3 currency, postage free.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. PRICE REDUCED TO 85¢.

Testing and Working Silver Ores.

The above is the title of an illustrated work of 114 pages, for miners and prospectors, by Chas. H. Aaron, which has just been issued by Dewey & Co. Mr. Aaron has managed to give many useful hints and suggestions, free from all technicalities, and in such a style as to be easily comprehended. It is written for the miner, with no chemical symbols or metallurgical technicalities to confuse those who are not chemists or metallurgists. The following summary of the contents of the work will give an idea of its scope.

Under the heading of the first chapter, "Testing Ores for Silver," we find paragraphs on ore formation, test for silver, with heat and water, acid or blow pipe. In speaking of testing for a process, the extent and richness of ore is considered, smelting ores, selecting and working sample, appliances for testing, roasting, etc. Under the head of "Working Ores" the author describes Aaron's process, has something to say of superheated steam, preparation of dichloride of copper and protochloride of copper, use of copper and iron, quantity of chemicals, carbonate of lime, chloride ores, amalgam, Futch's process, etc. He also describes the methods of working roasted ores, treatment of base metals, stirring, heat of furnace, want of sulphur, etc. Under the head of "Leaching Processes" are the titles, Smelting, Mexican process, Chilean process, Krochne's process, etc. Under "Pulverizing Machines" are described the astrata and its construction and operation, stamp batteries, screens, Crocker's trip-hammer battery, Paul's pulverizing barrel, Kendall's battery, Noice's pulverizer, a cheap rock breaker, etc.

In speaking of amalgamators the author describes a cheap amalgamator, grinding the ore, directions for making a barrel, preventing mechanical wear, use of quicksilver, copper in bars, Freiberg barrel, cheap barrel, trough, barrel on rollers, Aaron's amalgamator, separator, etc. He describes an improved retort, roasting furnace, furnace tools and furnace building. Among the miscellaneous mention may be found Aaron's leaching apparatus, with two or three different arrangements, a small mill, sampling tailings and settling tanks, dichloride of copper, etc. Mr. Aaron is a practical miner, of long working experience on this coast.

The book is a serviceable one for miners' and prospectors' use. Price, post free, (in leather,) \$2.00. Address Dewey & Co., MINING AND SCIENTIFIC PRESS, 224 Sansome Street, San Francisco.

The Explorers', Miners' and Metallurgists' Companion.

Comprising a Practical Exposition of the Various Departments of Exploration, Mining, Engineering, Assaying, and Metallurgy,

Containing 672 Pages and 83 Engravings,

BY J. S. PHILLIPS, M. E.,
Of California, a Practical Operator for Thirty-four Years; Explorer, and Resident in the Pacific States and Territories for the past Eight Years.

PRICE—bound in cloth, \$10.50; in leather, \$12. Forwarded by mail for 50c. extra, at the MINING AND SCIENTIFIC PRESS OFFICE, by DEWEY & CO.

UNITED STATES Mineral Land Laws, Revised Statutes, AND INSTRUCTIONS AND FORMS UNDER THE SAME.

We have just issued a pamphlet containing the General Mineral Land Laws of the United States, with instructions of the Commissioner of the Land Office. The contents of this pamphlet comprise all of the Government laws with relation to mineral lands of interest to the mining community, as follows: Mining Statute of May 10th, 1872, with Instructions by the Commissioner of the Land Office; Mining Statute of July 26th, 1866; Mining Statute of July 9th, 1870. Forms required under Mining Act of May 10th, 1872, as follows: Notice of Location; Request for Survey; Application for Patent; Proof of Posting Notice and Diagram of the Claim; Proof that Plat and Notice remained Posted on Claim during Time of Publication; Register's Certificate of Posting Notice for Sixty Days; Agreement of Publisher; Proof of Publication; Affidavit of \$500 Improvements; Statement and Charge of Fees; Proof of Ownership and Possession in Case of Loss or absence of Mining Records; Affidavit of Citizenship; Certificate that no Suit is Pending; Power of Attorney; Protest and Abandonment of Claim; Mineral Affidavit; Proof that No Known Veins Exist in a Placer Claim, etc. There is also given the U. S. Coal Land Law and Regulations thereunder. The work comprises thirty pages, and will be sold, post-free, for 50 cents. It should be in the hands of every one having any mining interests. DEWEY & CO., Publishers of the MINING AND SCIENTIFIC PRESS, S. F.

WOODLAND, CAL., Aug. 8th, 1876.
MESSRS. DEWEY & CO.—Gents: Your letter containing the patent for my Centennial Churn has come duly to hand, and you will please accept my many thanks for the prompt manner in which you attended to the business entrusted to your care, and I will take great pleasure in recommending you to any one having anything to attend to in your line. I am having a number of the churns put up, which will be ready for sale in a few weeks.
Yours truly,
JAMES ROOT.

\$1,000 Challenge Ore Feeder,

AWARDED FIRST PREMIUM

At the Tenth Industrial Fair of the Mechanics' Institute.

It may be considered as now fully demonstrated, by careful and long-continued experimentation, that the plan upon which a perfect ore feeder must be constructed is that of the carrier, and not that of the shaking table. Uniform and accurate feeding is not possible upon the latter plan. The ore must be evenly carried, upon a steadily advancing plane or table, to the line of discharge, and there simply dropped. Spasmodic or jerky contrivances will not answer the purpose.

REFERENCES.

A letter received from the Julian Mill, Newcastle, says of the Carrier Feeder: "It is the most perfect Feeder we have ever seen; don't see how any mill can do without them." A letter from Mr. C. C. Belding, of Amador County, speaks in the highest terms of them. "Two of the machines were shipped to the Bunker Hill Mill, also Gover Mill, Amador County." Mr. Stevenson, of Boston Mill, Gold Hill, Nevada, says they are the best Feeder he has ever seen. "Soulsby Mill, Tuolumne County." California Company, Nevada City. Omaha Gold Mining Company, Grass Valley. St. Patrick Mill, Placer County.

\$1,000 CHALLENGE.

Backward in Coming Forward.

C. P. Stanford Fails to Come to Time on the Challenge of \$1,000 to Test the Merits of His Ore Feeder as Against Mine. The Challenge is Still Open to Him or any one else. GENTLEMEN, Put up or Shut up.

A letter has been received from the Crescent mine, Plumas County, in which it states that the Tulloch is a failure as against the \$1,000 Challenge Feeder of Hendy's.

We warrant the machines to give perfect satisfaction, and to be a better and more durable Feeder than any other in the market, and will sell them as cheap as any other of its class.

Compound Steam Pump.

The great saving of steam, and consequently of fuel, by the expansion of steam as developed in "cut-off" and "compound" engines, is a well established fact in engineering, and one very generally known by those interested in the economical consumption of fuel. The inventor of the compound pump described here has applied the principle on which compound steam engines are constructed to steam pumps, and has done so in a highly successful manner. The mechanism, *modus operandi* and exterior appearance of this pump will be understood on reference to the perspective view, longitudinal and transverse sectional drawings on this page.

The elongated piston has two ends provided with packing, and has a cylindrical portion of a lesser diameter extending between the said ends, the said portion being fitted to work steam-tight in a central partition in the cylinder; two annular chambers are thus formed, into which steam is admitted to act upon the smaller areas of the piston ends, and it is afterward expanded into the spaces between the piston ends and the cylinder covers, to act upon the larger areas of the said piston; a double cylindrical valve regulates the movements of the steam, each half of it being formed with a passage to connect two ports through which steam passes from the annular space to the space between the piston and the cylinder head, and also with a passage which connects the larger steam space with the exhaust passage. Steam is admitted into a space between the two parts of this valve, and finds its way by suitable openings into the end spaces between the said valve ends and valve box covers; said end spaces are connected by passages with ports formed in the aforementioned partition, and as the piston moves to and fro, passages formed in the said piston establish a communication between the said ports and a port leading into the exhaust passage, thus relieving the valve from pressure on one end and causing it to be quickly pushed in that direction by the steam at the opposite end; the parts are all so arranged as to provide effectually for sufficient steam to cushion both the piston and valve so as to prevent striking under any ordinary circumstances.

The pump delivers a constant stream, will force to any height, and can be worked either with steam or compressed air. The indicator diagram given here is a fac simile of one taken from one of these compound cylinders, and a study of it will demonstrate the great economy of such a pumping engine in comparison with the direct-acting steam pumps that must use a cylinder full of steam at each stroke. Attention is called to the very short passage ways for live steam between the valve and the high pressure piston, thus insuring less waste of steam from steam passages than is ordinarily the case. The special advantages claimed for this description of pump are that it has only two moving parts, except the pump valves, thereby reducing friction to a minimum; that the steam having performed its work in the high pressure space, is afterward expanded, thereby extracting all the power possible from it, and effecting an enormous saving in fuel as compared with ordinary high pressure direct-acting steam pumps; that the high pressure and expansion are both carried on simultaneously throughout the entire stroke, thereby maintaining a more uniform aggregate piston pressure to the end of the stroke than would be possible with high pressure and expansion in one chamber, and that it is simple, compact, durable and portable, and can be used without expensive foundations.

In order to arrive at a correct estimate of the economy effected by this pump, the *Technologist*

says that Mr. J. Haug, a mechanical engineer, has made a comparison between a 12-inch compound pump with a single cylinder of the same power, and the result of a careful investigation shows that with the single cylinder pump there is an increase of consumption of 60.75% over the compound. The inventor, Mr. William Walker, an engineer of Manchester, England, has avoided the fault of complication in this

WALKER'S COMPOUND STEAM PUMP.

pump, it being as simple as any single cylinder pump, and much simpler than some of that description.

These compound steam pumps are being made

five years, but more especially the past fifteen, has made a large body of Americans good miners, and good experts as well; and it can be said, further, that the first-class American

Americans as Miners.

[Written for the Press by ALMARIN B. PAUL.]

Mining by Americans, as yet, can hardly be accepted as a business for a life-time pursuit, but more one to turn their hands to for the time being, and for trying their "luck."

This "trial of luck" during the past twenty-

never so substantial; it does not "hold forever," and he never worries if it does not. He does not work for his grandchildren, but for the present, calculating his children will have the same privileges. Two men pounding at one drill does not suit his notions of economy, therefore the idea is suggested of doing the work single-handed, and, with his giant explosive, doubles the execution at half the expense.

The American miner, in fact, is getting tired of even single-handed drilling, and is about concluding, for the future, to stand by, "boss" the machine, and save his muscle. He is an average mechanic, studies mechanism, and wonders how to get rid of hard work; and by his genius, in the coming future, close by, we are going to mine wholly by machinery. In fact, we can do it now, both on a large and small scale, by the universal adoption of the Burleigh, Ingersoll and Slater drills.

The same spirit which seeks expedition and cheapness in mining applies equally as strongly in milling the ore. When it is upon the surface, he wants the bullion from it in his safe before night, and to that end has it dumped into the mill, at will unlocks his safe, and "presto, change," there is the metal. This life and expedition of our mining operations has not been equaled on the face of the globe. It is purely American, and a condition of mining activity which every country is readily falling into, and which every foreigner of snap loves. There is no pursuit Americans are so well adapted to as mining, and why not more turn their attention to it? What will make greater prosperity for the whole Union is for the American people to accept mining as a vastly important and legitimate business, as having as much reward for labor, caution and capital as trade, agriculture, commerce or manufacture.

We have in California, Nevada, Arizona, Oregon, Colorado, Montana and Idaho, millions of leads with millions piled on millions of wealth, much of which can be had simply by locating, only wanting the hand of labor, and the favor of capital. We have also in the United States, East, West and South, a large idle yet industrious population, crying for work and prosperity, and who could soon turn a ready hand to gathering these treasures, relieving their wants and enriching all.

Mining in the past, and also in the present, has its parasites, which destroy its vigor, and this is stock gambling. A distinction must be better drawn between mining as a business and "mining" as a paper gamble. Let operations be conducted with the business vigor of manufacturing, and success will be even more certain. Let capital be more trusty to the deserving, and seek to build up legitimate mining operations, which may be accepted as the precious blood of business life.

COPPER.—By James Lewis & Sons' report on ores and metals we see that quotations for copper in Liverpool on the 1st inst. were as follows: Bars £76@76 10s, for good ordinary brands; £76 10s@77 10s for picked brands; ore, 14s 9d@15s, and regulus, 15s 3d per unit. The business transacted in Chile bars in December was on a very limited scale, the purchases being chiefly from second hands, and the fluctuations in

value have been covered by a range of £2 per ton—from £77 to £75—the closing value of good ordinary brands being £76 10s. Chile exports to December 16th are 53,462 tons fine, against 50,107 tons in 1875. Stocks of West Coast produce are 14,560 tons fine against 14,170 tons on the 1st ult.

SECTIONAL VIEW OF WALKER'S COMPOUND STEAM PUMP.

with all the ordinary sizes of steam cylinders, to meet the duty required for different altitudes and pressures. They are furnished at or about the regular prices of ordinary steam pumps. The sole agents for these pumps in this city are Messrs. Parke & Lacy, mining machinery depot, 417 Market street.

miner is more complete in his money-making operations than the average foreigner who has been reared from childhood in the work. While the latter mines by old rules, the American miner makes a rule suited to surrounding circumstances. He can turn more short corners, and do more with less money. His work is

CORRESPONDENCE.

Mining in Deer Lodge County, Montana.

(From our own Correspondent.)

Here, as in other counties of the Territory, the attention of miners is fast turning from placer and gravel mining as they grow less profitable to quartz. Near Blackfoot a fine copper lead has been opened and worked for nearly a year. From a cut along the lode it had been found to have a width of from eight to ten feet, the whole containing copper ore, with from six inches to four feet of carbonate ore, running 44% in copper. Upwards of 100 tons shipped to Baltimore brought \$4 per unit, or \$17-600 per 100 tons. The whole of the ore at the depth of 50 feet was thought to run fully 20%. Two other lodes were said to run parallel with this, all of which are owned by Messrs. Dorr & Arnold.

Some Good Placer Mines

Have been found on my way around the county, which seem worthy of notice.

The claim of Moore & Quigley, on Carpenter's bar, paid last season from \$9 to \$10 per day, or from \$2 to \$3 to the man after paying for water.

The Bedrock Fluming Co.,

Green, Pounds & Strickland, get a gross yield of about \$13,000, and made it pay well, as the principal part of the water used belonged to the company. No claim in the vicinity of Blackfoot turned out so well, perhaps, as that of Mr. Collins, which was reported as yielding \$100 to the man, and netting him about \$10,000 for the season.

The claims in California gulch, five miles from Washington, and owned principally by Messrs. Jackson, Keyes and Lusk, are well supplied with water and paid from \$12 to \$14 per day to the man. In Jefferson gulch, two miles east, the claim of Rule Bros. paid from \$9 to \$10. With a greater amount of pressure could be made to yield double the amount.

The Pioneer Co.,

At Pioneer, which have been [at work for the past ten years, have usually received for one season from \$2,000 to \$12,000 per share, the last year's return being about \$8,000. Other claims have not done so well.

At Emmetsburg,

Healy Bros. have a drift claim of 1,300 feet in length and 60 feet in width, of pay gravel, that yielded for drifting and washing, from \$9 to \$10 to the man. Messrs. Ferguson, Hennesy, and others, have one mile of bar and gulch considered good for \$5 or \$6 per day, that will last for 10 or 12 years.

Butler, Smith & Co. have a mile and a half that paid during water season at the rate of \$20 to the man. The instances given are sufficient to show that the placer mines are not yet "played out" in Montana.

Quartz in Elk Creek District.

The Radical and Lady Nixon has been opened to the depth of 80 feet, showing a two-foot vein of gold bearing quartz, lying between the limestone and the granite. The whole of the ore is worked and averages \$40 per ton. Owned by Messrs. Jones, Nixon & French.

There are four other lodes here developed about to the same extent and exhibiting rock of a similar character.

Several Promising Quartz Claims

Were heard of on Boulder Creek, 12 miles in a northerly direction from Philipsburg. The Sandy Brown, 23 feet in width, gives average assays of \$45 per ton. The Princeton, 20 feet, with eight feet of very fine ore, assaying from \$100 to \$500, according to report. The Emerson, owned by Mr. D. Emerson and others, situated on very high ground, 500 feet above the creek, is eight feet in width, giving assays as high as \$200, the ore containing some galena and said to be easily worked.

The Raritan, Saranac, Mediterranean, Crown Prince and Tigress were spoken of as good locations. The greatest depth reached in this district is probably not more than 30 feet in any case, but high hopes for its future are entertained.

Philipsburg as a Mining Camp

Stands very high in the county, and may, in fact, be deservedly ranked among the very best in the Territory. Most of the mines now worked lie in the limestone, in a belt of lodes not far from the granite. Some locations are in the granite, and sufficient developments have been made in the district to lead to the conclusion that there is a good contact vein between the two principal formations. So that if any one has a fancy for segregated deposits, pipe veins, true fissure or contact, he can be gratified, and is likely to find good ore for some time to come, in any of them.

The principal characteristic of the base milling ores is that they are enclosed in manganese, while much of the vein matter is of iron. They

are accompanied with arsenic, antimony, zinc, lead and sulphur; usually in sufficient quantity to require roasting. The black sulphurets are everywhere found and may be said to predominate as silver ores, and usually very rich. Owing to the shortness of my stay at Philipsburg, as well as to the state of the weather, only a few mines were visited, which will account for any meagerness of detail that may be apparent in reference to one or more of the most prominent of the district.

The Northwestern Company,

Mr. R. H. Lee, superintendent; incorporated stock held mostly in Philadelphia. They were at work on the Speckled Trout, sinking a shaft of three compartments (one to be used as a ladder way), with the view of facilitating their operations and making further explorations, the shaft having already reached the depth of about 200 feet. In the meantime, ore was being extracted through the incline on the vein, which kept their large 10-stamp mill busily pounding away. It is one of the best equipped in the Territory, being provided with a Blake rock breaker, four Bruckner cylinders for roasting and chloridizing, amalgamating pans, settlers and all the usual appliances for the successful working of silver ore. The Purvine pan (of which more hereafter) was first introduced here. No figures were obtained as to the present value of ores coming from the mine. Its past prosperous career is too well known to need repetition. Of its products, a beautiful specimen of wire silver was received, as a Christmas gift, from Mrs. Pardee, of Philipsburg.

The Freeman Lode,

Near the Northwestern company's mill, shaft 105 feet, and following the quartz the whole distance down. The full width of ore not yet ascertained, but thought to be fully 20 feet. Assays were reported from \$25 as high as \$250. Property of Mr. C. N. Freeman.

The Algonquin,

Lying in the same limestone belt, is opened by a tunnel of 265 feet and a shaft of 50 feet below the level of the same, and also a drift of 100 feet along the lead, showing a very large body of high grade ore, from four to nine feet in width. The walls are solid magnesian limestone, and about 175 feet apart. The outlook for the company is exceedingly flattering.

The Hope Mining Company,

Col. L. W. O'Bannon, superintendent, has two shafts—the deepest 100 feet and another of 80 feet—an incline also of 125 feet, disclosing segregated deposits of rich sulphurets ores incased in the limestone. They are free milling, and give an average of \$60 or a little upward to the ton, some rich pockets yielding from \$6,000 to \$12,000 per ton. The mine has paid well for the past year, besides leaving a large supply of all necessities on hand for future running. The affairs of the company seem to be in a very prosperous condition. They own several claims, such as the Cliff, the Comanche, Lady Bryan, Wabash and others, some of which are looked upon as very promising. Their mill is of the most substantial character, and the 80-horse engine, said to be one of the best to be found of the same capacity, having been designed and built by Mr. J. S. Collins, the present engineer at the mill. Although forgotten in its proper order, it is not too late to say that the timbering of this mine is so admirable as to deserve special mention, being seldom equaled here or elsewhere, and the entire credit being given by the superintendent to Mr. Wm. Lowry, his present efficient foreman.

The second claim on the

Comanche Lode,

Is owned by Dr. J. M. Merrell, et al.; shaft 115 feet, vein of free milling ore 5 feet, running about \$60 in silver.

The Silver Bend, the property of Messrs. Merrell & Ulrey, 1,500 feet in length, shaft 40 feet, with other developments, has 7 feet of free milling ore, also said to average \$80.

The Murray & Durfee S. M. Co.,

Have a claim one and a half miles east of Philipsburg, and above the mill of the North Western company, that has been opened by a shaft 60 feet, disclosing a body of base milling ore of rather high grade, which is, at least, five feet in width. A tunnel has also been run 250 feet in length to tap the vein when reached at about the same number of feet from the surface. The lode, from examinations made in the shaft, has every appearance of a true contact vein, lying between the granite and limestone, the former being found as a well-defined hanging wall. As no drifting had been done the distance to foot-wall could not be determined.

From 60 to 70 tons on the dump was estimated by Mr. Pardee, an experienced miner of the district, to cost \$150 per ton.

The Salmon,

Situated near the Speckled Trout and the property of Messrs. Holland & Estell, has two shafts of 30 feet and another of 46 feet, showing four feet of good milling ore, that has worked \$98 per ton.

They had about 50 tons on the dump, 1,200 patented and said to lie between the limestone and the granite, although no opportunity was had for settling the question by a personal inspection. The same gentleman also owns the Little Emma, near the Hope, that shows a vein of from eight to nine feet at the foot of shaft that has worked upward of \$70 per ton.

The Forest and Granite Mountain,

From what could be learned of it, is situated in

the granite, and looked upon as a true fissure vein of about nine feet in width.

It is represented as averaging \$150 in silver and about \$15 in gold. It is situated about one and a half miles further east than the limestone belt, and is owned by Messrs. Merrell, Holland & Estell. The Bonanza, owned by Ulrey & Co., together with many others in the district, were spoken of favorably.

Before closing my account of the mines at this prosperous camp, thanks are due to the different superintendents, and others, for needed information and frequent courtesies, and particularly to "Mein Freund Kaiser," whose delight is to make a stranger feel happy and at home. May he live long to run the Kaiser hotel.

A few condensed notes from the neighborhood of Georgetown must be given at this time, as the mines of Butte coming next in order will require a full letter.

The Pyrenees,

Kelly & Cameron owners. Tunnel 275 feet, 135 feet of which follows lode; from three to five feet of solid and continuous gold quartz, that works \$25 on average. Walls granite. Direction southwest, dip northwest, angle slight.

A dividend paying mine, the Eureka (Kidder & Merrell) eight feet—gangue, baryta. Ore carries \$100 silver and \$10 per ton gold. North Atlantic, four feet of gold quartz; runs \$30.

It is a matter of great regret that the Cable, one of the most remarkable of the Territory, is still idle from litigation, but strong hopes are entertained that a compromise will soon be effected. Splendid gold specimens are taken out near the surface, and placer mines are opened just below the mine, which have paid as high as \$600 to the box, or as much as \$39,000 a season, in a string of sluices. A. C. K.

Underground Condition of the California Mine.

In our last issue we gave briefly the annual reports of the officers of the California mine, one of the famous bonanzas. For want of space, however, we omitted that part of the superintendent's report referring to the workings of the mine, and now give them. Mr. Fair's report was as follows:

On the 1300-foot level no work has been done during the past year in the way of developing this portion of the mine, but all the drifts and winzes have been kept in repair. The northern 500 feet of this level, as well as the ground between this level and the 500-foot station, remain undeveloped.

On the 1400-foot level the drift running lengthwise in the vein has been run north, and has connected with the Ophir mine, securing ventilation. No ore of value has been found in the northern 250 feet of this drift, yet it may exist to the right or left of this drift. The proposed cross-cuts, Nos. 4, 5 and 6, have not yet been run on this level. In cross-cut No. 3 a winze has been sunk, connecting with the ore-breasts which are now being worked on the level below. This winze passed into good ore 17 feet below this level. Between cross-cuts Nos. 1 and 2 we are now breasting out high-grade ore above this level. How far it will extend upward is not known, as the level above is yet undeveloped. From the work already done it is evident that this ore body is extensive and of great value.

On the 1500-foot level much work has been done during the past year, and much ore has been extracted. Cross-cuts Nos. 4, 5 and 6 have not yet been extended to the east wall, and the full extent of the ore is so far unknown. The northern 200 feet (excepting a few feet on the north end) and the southern 250 feet of this level show bodies of ore of large extent and of great value. All the winzes above the level, also all the drifts and cross-cuts on this level are in good repair.

On the 1550-foot level, the drift running lengthwise in the middle of the vein has been extended from the south line to within a few feet of the northern boundary of the mine, passing all the way through excellent ore. The various cross-cuts run on this level at intervals of 100 feet, and the various winzes connecting with the level above, together with the northern 200 feet of the level below, show the ore to be of much greater width and of a far better quality than on any of the levels above. As the three cross-cuts in the center of the mine have not been extended entirely across the ore body on this level, the whole width of it has not been ascertained. Between cross-cuts Nos. 2 and 3 a double winze has been sunk to a depth of 128 feet, through ore of excellent quality. Owing to the flow of water a cross-cut could not be made from this winze. Within the past 10 days, however, this winze has been freed from water to the depth of 100 feet, and a drift from it started south, which is intended to connect with the drift that is now being run on the 1650-foot level of the joint shaft of the California and Con. Virginia mines. This drift from the winze has now advanced 16 feet, and continues to pass through ore of the same good quality as was found in the winze. Another winze was sunk from this level in the Con. Virginia mine to the depth of 127 feet, passing all the way down in ore of great richness. No cross-cut was made from this winze on account of the heavy flow of water. The developments made by these winzes prove that the same ore body, which exists on the levels above, continues to

these lower depths, with an increased value to the ore, and I have no doubt that it is of great width.

On the 1600-foot level the ore breast is now opened in a square of 80 by 80 feet. This breast has not yet been extended to either the east or the west wall of the ledge. Considerable ore has been taken from this locality, having been transported from the Ophir mine to the Ophir shaft. This mode of raising the ore was necessarily adopted because our own shaft (the Con. Virginia shaft) does not extend below the 1550-foot level. This ore breast is directly under cross-cut No. 6, on the level above. The north face is 30 feet from our northern boundary line, and it is now being worked northward and upward. The ore is of a very fine quality, and of a much higher grade than that above on the 1500 and 1550-foot levels. On this level we have a drift which runs south in the ore body, connecting with winze No. 5, sunk from the level above. It then continues south and connects with the deep winze which was sunk 128 feet below the 1500-ft level. This drift passes all the way through rich ore, except for a few feet, where the ore is of low grade.

The time for the convenient and advantageous working of these lower levels will come when the drift, which is now being run from the California and Consolidated shaft, on the 1650-ft level, has reached the ore body. This drift is now 610 feet from that shaft, and will reach the vein some time during the present month. Connection will then be made from this drift with the deep winzes spoken of above, which will give new facilities for extracting ore from these lower levels, and at the same time will create additional ventilation for the mine. I may here remark that this drift would have been in the ledge five months ago, had it not been for the great influx of water in the Consolidated and California shaft, which has prolonged the sinking of the shaft, and consequently delayed the running of this drift and the opening and working of the lower levels.

The Consolidated and California shaft (the joint shaft of the California and Consolidated Virginia mines) is now down 22 feet below the 1650-foot level, and the work of sinking is still going on. The progress in sinking this shaft has been slow on account of the water we have had to contend with from 200 feet from the surface down; the flow of water amounting to from 43 to 47 inches, miners' measure.

All the appurtenances to this shaft, such as the main building, an extensive machine shop, the ore house, the hoisting and pumping machinery, the pumps, pump bobs, water tanks, etc., are complete in every respect. Everything has been constructed on a scale and in a manner commensurate with the large future requirements of the two mines. The surface station of this shaft and the stations in the shaft have been made double, one immediately above another, and two cages, called a double-decker, are employed for hoisting ore, so attached one above the other as to exactly meet these divisions of the stations; both cages being loaded in the mine and unloaded at the surface at the same time. By this method time is economized in raising ore. From the surface station, two substantial railways, one directly over the other, are laid to the California mill, near by, over which the ore as it comes to the surface can be taken to the mill. This mill is capable of reducing 300 tons per day. An ore house of 3,000 tons capacity has recently been erected, from which ore can be shipped by railroad to other mills.

The facilities for landing wood, timber, and other mining supplies, and for shipping to mills the ore raised through this shaft, have been much improved by the construction of a branch track from the Virginia & Truckee railroad, which passes on both the upper and lower sides, in close proximity to the works.

The cost of this shaft and all its appurtenances, together with all the real estate acquired for the purposes of the shaft, amounts, up to January 1st, 1877, to \$820,000. Protection of these works against fire has been secured by a complete system of water pipes, hydrants and hose, with a plentiful supply of water under heavy pressure.

A portion of the ore extracted from the mine during the past year, has been raised through this shaft, having been transported from the mine through a drift which connects directly with this shaft on the 1500-foot level. This is a large drift, well timbered, and laid with a T-rail track, the same as is used in all the drifts and cross-cuts on the 1500-foot level. In addition to being a convenient thoroughfare for the transportation of ore, this drift aids materially in the ventilation of the mine.

Our supply of wood and timber is ample for present requirements, and without any addition to it is sufficient to meet our wants in the event of a storm of a month's duration.

We have facilities for the melting and assaying of all the bullion produced from the mine in the department which has been constructed for that purpose, in the immediate vicinity of the mining works, and which has been furnished with all the requisite apparatus and materials for doing that work, both for this and the Consolidated Virginia mines.

With the expectation of soon overcoming all the impediments which have been hinted at above, as having stood in the way of our operations in the mine, and that the necessary connections will soon be made for working the lower levels to advantage, I anticipate, from the indications which are before us, that the work of the present year will be crowned with unparalleled success.

SCIENTIFIC PROGRESS.

Light and the Eyes.

Prof. J. Dewar lectured on the 16th inst., at the London Institution, on "Light and the Eye." The drift of the lecture, says *Iron*, was to show that the action of light on the eye can be estimated by its electrical effects. The chemist knows that in chemical changes heat changes are manifested, but as electrical tests are now so much more delicately constructed, these can show changes which our present heat measures cannot. For the purpose of the lecture a Thompson reflecting galvanometer was used. The first experiment shown was the effect of light on two plates of metal coated with chloride of silver, and arranged to show the electric effect by the action of the galvanometer. The experiment proved that the electric effect of light was great, the reflection of the galvanometer indicating that beyond the usually recognized photographic effect there was a decided electrical effect. The question what kind of light produced this effect was then considered, and colored lights were used on the plates. Red, which has a small photographic effect, was shown to have a small electric effect, while violet and ultra-violet, which have a large photographic effect, had a great electric effect. The next point referred to was the electrical effects produced by muscular action. This was shown by having two troughs of gutta-percha filled with a saline solution. A skein of cotton-wool, soaked with the solution, connected the two. By the means of clayey electrodes, a circuit was completed with a battery; and when it was shown the connection was complete, every "putting-on" of the battery produced a movement of the connected galvanometer. Then the professor used his own body in place of the skein to complete the circuit, and in place of battery action used the muscular contraction of his hand. The muscular contraction had the same effect on the galvanometer as had a battery action. The electric effect of muscular action being shown in this and other ways, the passage of electricity through the eye was illustrated, the eye of a recently-killed frog being used to show the effect of light on it in producing electrical effects. The eye was placed in contact between two electrodes, such as were used with the skein of cotton. When light was thrown on it from a lime-light, the electric effect, as told by the galvanometer, was unmistakably seen. Prof. Dewar said that a lobster's eye was very favorable for such an experiment. He had also had it tried on himself. He lay on his back, and a "pudding" was made round his eye, in which a saline solution was poured. One electrode was put in this, and his hand made the other. An observer let in varying amounts of light on his eye, and noticed the effect on the galvanometer with which he was connected. The results quite accord with those of an eye from a recently-killed cold-blooded animal. Such work as this, with carefully-recorded tabulated results, must increase our knowledge of what the action of the eye really is.

Chemistry in America.

During the last year there was formed in New York City a society of chemists, under the title of "The American Chemical Society." Dr. John W. Draper delivered the inaugural address before the society, on November 16th, which is given in full in the *Popular Science Monthly* for January. The address was not only an able one, but, in some of its parts, most beautiful. No synopsis would do it justice, but we give a paragraph, which speaks more particularly of what has been done in chemistry. "Of our own special science, chemistry, it may truly be affirmed that nowhere are its most advanced ideas, its new conceptions, better understood or more eagerly received. But how useless would it be for me to attempt a description in these few moments of what Prof. Silliman found that he could not include on more than 100 closely-printed pages, though he proposed merely to give the names of American chemists and the titles of their works! It would be equally useless and, indeed, an invidious task to offer a selection; but this may be said, that among the more prominent memoirs there are many not inferior to the foremost that the chemical literature of Europe can present. How unsatisfactory, then, is this brief statement I have made of what might be justly claimed for American science! Had it been ten times as long, and far more forcibly offered, it would still have fallen short of completeness. I still should have been open to the accusation of not having done justice to the subject."

MAKING FABRICS UNFURNISHABLE.—The credit belongs to Mr. Dion Boucicault, in Wall-lack's theater, for practically demonstrating to deputies of the Fire Department, fire insurance companies and others that canvas scenery prepared with tungstate of soda and silicate of soda was totally unfurnishable, that a gas flame made scarcely any impression when it came in contact with it, and when submitted for a long time to a very large gas jet, all that happened was disintegration of the parts subjected to the gas flame, they falling in the form of ashes on the ground; but in no case was any flame communicated, nor could the fire possibly spread, from want of any inflammable material, canvas, ropes and wood-work being all made absolutely unfurnishable.

The Diamond Drill in English Geology.

The museum of the Yorkshire Philosophical Society, says the *Colliery Guardian*, has just received an interesting addition to its geological department by the gift of some specimens of rock, four inches in diameter, and varying from a yard to a few inches in length, showing the various strata which lie below Masham to a depth of more than 400 feet. They are the "cores" from an artesian well, which was bored last winter at the Well Garth brewery, Masham, to get an increased water supply for brewing purposes, and the owner, Mr. Thomas Lightfoot, instead of leaving them in some merely local collection, has just presented them to the York museum, where, in the course of a few days, they may be seen by the public, and will be most easily accessible for any geological investigation. The boring was done by the Diamond Rock Boring Company's process, which cuts the rock by means of a revolving circular metal crown studded with diamonds, and the portion cut out is drawn up in the form of small round pillars. These were carefully preserved in the order in which they came out of the ground, and they are, therefore, accurate samples of all the rocks in the particular district to the depth bored, and no similar collection is known in any museum in the neighborhood. The total depth of the artesian well from which the "cores" came is 435 feet, and it descends through shales and sandstones of various kinds in the carboniferous system to the millstone grit, which was found to be saturated with water, and from which there has been flowing, ever since it was struck, an unintermittent natural stream, without mechanical aids, of very pure, bright, soft water, at the rate of about 1,800 gallons an hour. The specimens are contained in eight large boxes, and are undergoing a careful examination by the honorary curator of geology at the museum (Mr. Reed, F. G. S.), preparatory to the society's monthly meeting, when they will form the subject of discussion. So much of our knowledge of the geology of any district is derived exclusively from an examination of the outcrops of rock, that it is especially interesting, more particularly in a neighborhood where there is hardly any mining, to be able to see actual specimens of the rocks which exist directly beneath a given place, and geologists everywhere may be thankful to Mr. Lightfoot for having made these specimens public property; while to the Yorkshire Philosophical Society—which, although intended to aid science generally, was formed more especially to promote the study of the geology of Yorkshire—they are of very great value, for the society's collection contains nothing which is at all like these "cores," which, during the last week, have been handed over to it.

Mica Scale Pans.

The following note read at the late meeting of the American Chemical Society, by W. L. Land, will be interesting to our workers in laboratories: Our best analytical balances of 200 grammes capacity are usually fitted with a pair of movable glass pans, or watch-glasses of three inches diameter, and weighing about 30 grammes. To relieve the delicate bearings of the instrument from this unnecessary weight, and also to increase the capacity of the same in a commensurate degree, I employ as a substitute for these glasses a pair of three-inch mica disks, which weigh less than two grammes, the "gravity bob" if necessary being adjusted to this change. After three years' daily use, I find these mica pans as good as at first. The abrasion of the mica surface by a platinum spatula (used in weighing), during this period is scarcely visible. The mica used for this purpose is a pure, hard article found in North Carolina. It is as clear or transparent as flint glass when split sufficiently thin for the purpose to which it is here applied. Another great advantage of the mica is found in its flexibility, which enables one to dispose of weighed material with rapidity and exactness, as by bending the mica into a semi-cylindrical form it can be adapted to the mouth of a flask, crucible, etc., with the greatest ease.

Small discs of this material also form excellent transparent covers for platinum crucibles and capsules, where the heat applied does not exceed low redness, as in the conversion of oxalate into carbonate of lime, etc. I feel confident that no member of this society will ever abandon the use of mica scale pans, after a thorough trial of the same.

BURIED FORESTS.—The discovery of a subterranean forest just below the surface of the Thames river, is attracting a good deal of attention in England. The oak, the alder and the willow are the principal trees found. These retain their vegetable character, but other signs show that the forest belongs to the period of the elk and the red deer in the south of England. There is such a subterranean forest in the New Jersey flats; it consists chiefly of cedar trees, which have become very hard, and in some instances have paid the cost of extraction. The time of their burial has not yet been determined, but the cause is undoubtedly due to the slow subsidence of the State of New Jersey, which, it is authoritatively stated, sinks now at the rate of about 16 inches in a century. If this sinking has been uniform, 3,000 years would have caused a sinking of 40 feet, and thus the forest may, 3,000 years ago, have been 30 feet above tide water, while now it is 10 feet below, and buried under the deposits carried on top of it by every flood.

MECHANICAL PROGRESS.

Sand in Iron.

The *London Mining Journal* gives an interesting article on the presence of sand in iron, and of the way in which it is proposed to escape the evil: Silica in iron is sand in the wrong place. In one form or another sand is found in most of our minerals; it is certainly dispersed throughout our coal and limestone seams, and it is combined with our iron ores. It is so refractory that it is not to be got rid of by the process of calcining either in the open or closed hearth, and it passes as a constituent of the coke, the lime and the iron ore into the blast-furnace, where it is impossible to wholly expel it, for it holds possession as silicon. The puddler and the other operators in the forge and the mill have to do battle with it, when it is desired from the pig to produce wrought iron of first quality as a malleable product. True, its presence will contribute to the making of a quality of sheets suitable, for example, to the making of cut nails, or strips for making gas tubes; indeed, will help to make puddled steel, for it has a tendency to deposit carbon, but when have said this we have pretty much exhausted the category of good service which, in iron-making, silicon is capable of rendering. The benefit of its services it will be seen is hardly more than negative in the best of cases, since the value of nail-sheets and tube strip is only trifling.

It should not, therefore, be surprising that iron-makers should generally desire to rid themselves of the ingredient. Blast-furnace proprietors would gladly rid themselves of it in other than exceptional instances, but how to succeed is not clear so far as the ingredient is part and parcel of the pig. Less difficult, however, would be the attempt to cleanse the surface of the pig from the presence of sand. In truth, in this there is no practical difficulty. For silica as an incrustation upon pig iron the sand bed into which the contents of the blast-furnace is tapped is responsible. Running the molten iron of the blast-furnace into sand, thereby to shape the pig, is a practice which, though of very extensive application, would be more honored in the breach than the observance. It is impossible but that iron must pick up considerable quantities of sand, and thereby becomes seriously polluted. It is within the experience of men who use such iron in the forge and mill that the pollution may occasionally be calculated at one pound of sand to 100 pounds of raw iron.

The theme was some time ago ably discussed by foremost iron-masters in the Cleveland district, and it is now being taken up by the practical iron-makers of South Staffordshire, where the Forge Managers' Association have this week had one discussion upon it, raised by one of their number, and they are stated to have had so much to say upon it that it was found expedient to adjourn the debate. The remedy of the evil consists in that which the leading iron-masters pointed out—the tapping of the blast-furnace into chills of iron, and not into beds of sand. Doubtless the first cost of chills would be much greater than of sand, but it is not clear that in the long run the employment of chills would not prove as economical as the use of sand beds; for when the chills had become worn out they would be capable of being used up, either in the blast-furnace itself or in the refinery, whilst the improvement in the purity of the pig would increase the market value of the iron. Mr. I. Lowthian Bell has spoken upon the great economy which would follow upon the elimination of phosphorus from Cleveland iron and the transmuting of it into phosphoric acid. The day is not very remote when it will be resolved to further economize the refining of iron in the forge and the mill by the shaping of raw iron in chills and not in sand beds; and when that has come about puddlers will be deprived of sources of complaint pregnant of much dissatisfaction and ill-feeling, and many thousands a year will be saved in the British iron trade.

The Locomotive at Sea.

The *Iron Age* gives the following interesting account of an experiment to introduce locomotive engines in marine architecture:

Not long since the steamer *Novelty* was run ashore in New York harbor, near Fort Wadsworth. The steamer, which had been used as an excursion boat from Newark, New Jersey, during the summer, was on her way to Florida, where she was to run upon the St. John's river. Before she was out of the harbor she was struck by a schooner, and an eight-foot hole knocked in her bow, making it necessary that she should be beached to prevent her from sinking. The vessel was built at Chester, Pa., in 1869, for a novelty, by Mr. Gould, an Eastern man. The following are her principal proportions: Length, 216 feet; breadth of beam, 24 feet; and depth of hold, five feet. She is built of iron, and was of 339 tons burden.

In some respects this was one of the most novel vessels ever built. Her peculiarity was in her machinery, which consisted in two pairs of what might be termed locomotive engines, of

16-inch cylinder and 24-inch stroke, and two locomotive boilers 18 feet long and 54 inches in diameter. The idea was to use a light, fast running engine of the locomotive type, and so obtain great power with light weight and small boilers.

In railway practice it is found that an engine of 1,000-horse power is not much more bulky than the marine boiler of the same power. It has often been proposed to build a marine engine upon the plan of the locomotive, which should not only be light but powerful, and occupy very small space. To accomplish this, it is of course necessary that the engine be geared. Mr. Gould's idea was a good one, but unfortunately the vessel which he built was by no means fast; in fact, as a speedy boat she was a failure. Other engineers had the same idea, and one in this city was making arrangements to build a steamer with engines upon this plan at the time the *Novelty* made her trial trips; her failure in speed was so great that the gentlemen for whom the boat was to be built wished the plan altered. The difficulty was not, however, in the plan but its execution. To obtain the power from such small engines it is necessary that they should run very fast. It is said that the paddle wheels and gearing of the *Novelty* were not properly proportioned for the peculiar service, and "locked up" the engines, i. e., made them run too slow, hence a lack of power and loss of speed. Judging from appearances the hull also was not of a very good model. Probably at some future time, when this failure is forgotten, another experiment may be made in the same line, and if the calculations are correctly made, a fast, light and economical boat will be the result.

Using Putty.

A wood-worker writes as follows in an exchange: A good joint is not all required in making a complete finish on wood-work, and one of the greatest troubles met with by unskilled workmen is the removing all appearance of nail or screw heads, having been sunk beneath the surface.

Putty, unless rightly put in, answers a very poor purpose, especially when the work is ever to be exposed to heat. Heat expands iron, and the nail or screw head will lift the putty and make it show a prominence on the surface of the work.

Tacks or small nails may be driven so deep that putty will not necessarily reach the head, leaving a vacuum for the expansion, but for large nails or screws the plugging mode is the best. Sink the screws at least one-fourth of an inch below the surface, then square the hole and insert a plug of the same wood, precisely, as that in which the incision is made, and have the wood exactly correspond, that is, the grains to run the same way. Fit the plug with slightly beveling sides, so tight that when it is driven in solid, it will not reach the head of the nail or screw.

Apply glue to the sides of the plug before driving, and when well set, plane off the surface and sandpaper until the surface is level and smooth.

When putty is used it will be found an advantage to sandpaper thoroughly before filling the cavities, as dust of wood will partly fill the holes and prevent the putty setting in a solid bed upon the iron heads, and will be less liable to get lifted by expansion. Where large checks or cavities are to be filled with putty, the use of hot glue will greatly add to its durability. Moisten the putty with glue, just as it is inserted, and do not attempt to smooth up until it is thoroughly hardened.

HOISTING APPARATUS AND STAMP HAMMER.

The improved apparatus invented by Mr. P. Teiter, of Heilbronn, Wurtemberg, comprises a stamp hammer which is raised by hoisting or winding-up mechanism, and falls by its own weight between suitable guide rails. The said winding-up mechanism transmits the movement of a shaft which always revolves in the same direction to the hammer in such manner that the same is raised several times in a minute to any desired height, and the same in falling is not arrested by any obstacle. The working of the machine will be better understood when it is explained that it is driven by a strap running on a pulley, by which a regular rotation of the said shaft and a worm fixed on the same is obtained. The worm moves a worm wheel fixed on a hollow shaft, whereon is also fixed a ratchet wheel. For transmitting this regular rotating movement to the hammer he employs the following parts: A double crank, the shaft of which turns in the hollow shaft, pawls fixed on the double crank, and a driving pulley around which the cord for raising the hammer is wound. This cord is fixed by one end to a tension pulley, and by the other end to a hammer passing around the driving pulley and guiding pulleys. The lowest position of the hammer corresponds with the position occupied by the double crank as long as the cord is kept in tension. As soon as the hammer has fallen two teeth of the ratchet wheel will pull the two pawls, and in consequence thereof give to the crank a rotating movement. This movement is also imparted to the driving pulley fixed to the crank, and the cord is pulled during half a rotation of the ratchet wheel and the hammer raised. The foundation plate receives the bearings for the rotating parts of the machine.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

ALPINE.

EXCELSIOR MILL.—*Alpine Chronicle*, Jan. 20: The improvements at this mill are making good progress. The new 10-stamp battery is in, making it an 18-stamp mill. The furnace building is being inclosed, and next week Mr. O'Hara will make the necessary connections with his new furnace, preparatory to making a run, as the mill will soon be ready for active operations. The new boarding house is rapidly approaching completion. It will be very commodious and comfortable.

AMADOR.

VOLCANO TUNNEL.—*Amador Ledger*, Jan. 20: The tunnel of the Volcano company, intended to provide an outlet for the tailings so as to hydraulic the gold bearing deposits in Volcano basin, is now in nearly 350 feet. A full complement of men are busy pushing the work the whole 24 hours round. The rock gets harder and progress from henceforth must be necessarily slow. The tunnel advances at about the rate of one set of timbers, covering five feet, every two days. Nearly 1,900 feet remain to be excavated.

VOLUNTER.—All the water has been taken from the shaft. The work of prospecting is fairly under way. When work was suspended a year ago, the ore body almost pinched out. The present company have been drifting for the ledge, with gratifying success. Quartz of good quality has been struck during the week. The rock shows black veins all through it, and contains plenty of sulphurets. It is expected to improve in quality as the exploration of the ore body proceeds.

MOSTRUARD.—The clean-up of this mine at the Volunteer mill averaged, we are told, in the neighborhood of \$12 per ton—a very satisfactory crushing.

GRAVEL MINING.—The copious ruins which have fallen in the last few days will have the effect of starting the gravel claims throughout the county. The large mines at Fiddletown and Volcano have been idle for some time for lack of water. We expect to see these in full blast again.

Quite a number of miners have also been working along the creeks and in the gulches, taking out pay dirt ready for washing. They will now be enabled to clean up and realize something for the labor of months gone.

IONIA VALLEY COAL.—The Railroad Company control both the coal mines of Buckeye and Ionia. Nearly all the coal so far offered for sale outside of the county has been taken from beds at Buckeye. It would seem that this coal is of a much inferior quality to that of the Ionia mine, and the placing it on the market has not created a favorable impression of the adaptability of the valley fuel for locomotive, steamboat or household purposes. Now that the damage has been done, the company are trying to retrace the false step by shipping from the Ionia mine. Over 100 tons were sent below this week, and it is confidently expected that it will meet with a better reception than former consignments. The Amador Consolidated mining company have declared another dividend of 25 cents per share. The new hoisting works of the North Governor are completed.

CALAVERAS.

NEW TUNNEL.—*Calaveras Chronicle*, Jan. 20: A new tunnel is being run in the Brown gravel claim, Tunnel ridge, a little below the site of the old Mercer garden. The tunnel has already been driven nearly 200 feet in bedrock. The entire distance to be run, before reaching the channel, will approximate 600 feet. The new tunnel will permit the working of ground at the upper or northern end of the claim which cannot be conveniently got at through the old workings at the southern extremity. It can also be used for washing through if the owner of the claim should conclude to hydraulic instead of drifting as formerly. Mr. Brown is persevering and energetic in the prosecution of mining ventures, and we are perfectly willing to hear that his new tunnel has uncovered a bonanza any day.

NEW QUARTZ MILL.—The Hughes brothers have lately erected a 10-stamp quartz mill, at the gravel mine near the junction of the Ionia and the North Governor. The purpose of utilizing the machinery previously employed in running the hoisting works at the gravel claim. The mill is entirely completed and would have been in operation a couple of weeks ago but for the scarcity of water. The recent rain has increased the water supply so that crushing can be immediately commenced. The ledge from which the mill is supplied is located on the ridge beyond the Junction, to the right of the road leading to San Andreas. It has been pretty thoroughly prospected and the indications are good that it will develop into a valuable mine. Something like 30 tons of ore has already been hauled to the mill, and now that water can be obtained to run the machinery, we presume the stamps will be put in motion and kept at work.

UNION COUNTRY MINES.—*Notes.*—Work is progressing upon two new quartz mills at West Point. Messrs. Carey and Hall are the builders. One of the mills is being put up on the old Zacator mine and the other on the old Doyle ledge. Both mills will be run by steam. Favorable developments continue to be made at the Mina Rica. Fifty-four tons of rock, taken from the old Holmes mine near Mosquito, owned by Griswold & Co., crushed in Garland's mill, paid \$12 per ton.

EL DORADO.

ST. LAWRENCE.—*El Dorado Republican*, Jan. 18: The St. Lawrence still continues to look as well as it has at any time during the past two months, and the mine may now be said to be in thorough working order. A larger force will now be supplied on the 15th of February, and the mill will be started up, with a fine prospect of being constantly supplied with ore from that time forward. The first run may be counted on for from anywhere between \$50,000 and \$100,000.

NEVADA.

MOUNTAINEER.—*Nevada Transcript*, Jan. 21: One of the new and most promising developments recently made in quartz, in this vicinity, is on the ledge known as the Mountaineer, situated about 600 feet east of the Nevada and Province mines, on the north side of Deer creek, and running parallel with them. It was opened about two years ago, and over a year ago a contract was let to Jack Stiles and Thomas Miner to take out 500 tons of ore. They have been at work ever since, and have made good headway. Some of the crushings have yielded \$100 per ton, and it has all averaged over \$40 per ton. The ledge is 18 inches thick. There are about 30 tons on the dump now, and good judges say it is the finest looking of any rock ever taken out in the district. The owners are J. F. Carr, George Smith and John Miner. It is a very promising property, and the owners are justly pleased with it.

CONFIDENCE LEDGE.—We saw some very fine specimens of rock, recently blasted out of the Confidence ledge, in Washington township. It is a continuation of the Yuba mine. At this point the ledge is about three feet in width. The rock is very fine, and shows fair quantities of free gold, and we are told all rock taken out of the ledge thus far looks well. The owners of the mine are J. F. Carr, Mike Carver, H. A. Lord and others. The quartz interest of Washington township is attracting the attention of capitalists, and promises to be the best part of the county for mining.

YUBA MINE.—The Yuba mine, situated in Washington township, is looking up very encouraging now, and the company are in shape to do extensive and profitable work. A new 25-stamp mill has been erected, and is ready for operation. An Ingersoll drill is on the ground ready for work. The company employ between 60 and 70 men. The ledge is from four to eight feet in width, and the rock, we understand, pays in the neighborhood of \$30 per ton. The fortunate owners reside mostly in Grass Valley,

and the Coleman brothers are large stockholders.

THE GEORGIA MINE.—We noticed a few days since that the claim known as the Amos Laird ground, situated at the gap of the Sugar Loaf, and on the old river channel, was to be worked. A company has incorporated and will soon be ready for operations. The stock is divided into 50,000 shares, of the par value of \$10 each. The trustees are A. H. Hanson, J. L. Holland and Francis Hanson. The ground is called the Georgia mine. It is bounded by the Live Oak, Manzanita, Nebraska and Downey claims. There is an incline now down 400 feet to bedrock, and machinery is in place ready for work. The outlay required to be worked will be to run drifts.

MR. BECKMAN. while prospecting in the vicinity of Wood's ravine, the other day, picked up a piece of quartz about three by four inches and two inches thick, containing about 800 worth of gold.

A LONG TUNNEL.—*Grass Valley Union*, Jan. 20: The Deer Creek mining company are engaged in running a large tunnel, through which their claims at Mooney Flat will be worked. The tunnel is now in about 2,250 feet, and is in very hard rock. Two Ingersoll drills are kept constantly at work, and good progress is being made. When the tunnel is completed a large body of rich gold bearing gravel will be ready for the hydraulic process. Mooney Flat has the same character of gravel that has made Sucker Flat so famous. Mooney Flat is in Nevada county, a part of the claims of the Yuba. **GOOD CLEAN-UP.**—*Grass Valley Union*, Jan. 23: The Centennial mine is located on Osborne hill, and on the highest part of the prominence. Several crushings have been taken from this mine, and all of them have "cleaned up" large amounts of gold. Last Saturday a crushing was completed at John Smith's Orleans mill and a clean-up made. The ore crushed was 140 tons, and the yield from it was \$1,000, or over \$7 to the load. This is without counting the valuable sulphurets that have been saved, which will add considerably to the yield. The Centennial can now be placed on the list of dividend payers.

PLACER.

THE STORM.—*Dutch Flat Forum*, Jan. 10: The long looked for storm set in on Tuesday morning, and our miners are all wearing pleased countenances again. Owing to the continued drouth, the various claims in this section have been lying idle waiting for water, but will now probably soon be washing under full headway. The recent severe cold snap froze up the water in the ditch of the Cedar Creek mine, so that but about 40 inches is coming down. The superintendent took advantage of the circumstance and cleaned up a portion of the sluices in the Baker claim, so that that claim is now off fitting up and preparing to fire a powder blast in the solid gravel, which is nearly within reach.

BEAR RIVER.—The Centennial and Crisman companies are still making good headway in breasting and washing out the gravel, with satisfactory results. Whipple claims the gravel taken from this mine at present is said to be very rich. Some of the pieces of gold found weighed as high as an ounce. The indications are that this rich deposit of gravel is quite extensive. The Dom Pedro company as yet is having very poor success.

ALTA MINES.—The Shady G & I claim, owned by Andrew Larson, embraces 140 acres of ground, the northwest line of which is south, or immediately behind Barnard's hotel, and runs southeast to the Canyon Creek sawmill. The channel which passes through this mine is known to be a continuation of the Nary Red channel, which runs southeast, and has been traced by Mr. Larson and other miners several miles, via Canyon Creek mill, Hoy's Back, the Williams mill ranch to the bank of the American river, opposite Green Valley, where all traces of it are lost. From this point to the Hot Springs Back there was considerable prospecting done years ago by several companies in sinking shafts, running tunnels, etc., but the gravel was found to carry only gold enough to pay for hydraulic, for which purpose it is being held by its present owners. Canyon Creek passes through about the center of Mr. Larson's claim, cutting square across the channel, at which place the depth of gravel to the bedrock is only about 22 feet. From this enabling him to prospect the channel thoroughly by sinking 11 shafts, three of which were sunk near the center of the channel, showing the gravel to carry sufficient gold to pay for drifting, for which purpose a tunnel is now being run. The tunnel starts on the south side of the channel, in Canyon creek. It has passed through 100 feet of rim rock, and tapped the shaft zone deep in the top, which the gravel has stood and is being deepened. The gravel is of fine quality, and the ledge increases in size. The clean-up for the month of December was very near \$11,000, and a dividend of \$1.50 per share has been paid, with good prospects for regular monthly dividends hereafter.

THE RISING SUN mine at Colfax has again given evidence of its reliability as a permanent mine. The shaft zone deepened and deeper the ore improves in quality and the ledge increases in size. The clean-up for the month of December was very near \$11,000, and a dividend of \$1.50 per share has been paid, with good prospects for regular monthly dividends hereafter.

ANOTHER QUARTZ MINE.—*Placer Herald*, Jan. 14: An old quartz mine on Stewart's flat, about two miles below Newcastle, that for some cause had been abandoned for years, has, we learn on reliable authority, passed into the hands of a new company, composed of San Francisco capitalists and Placer county miners, who propose to reopen it at once. An old five-stamp steam mill stands at the mine, which will be fitted up and made to do service for the present. The shaft, which now is well filled with water, is about 150 feet deep. A short time only will be required to pump out the water and sluice both all in readiness, he expects to be able to be washing dirt in about three weeks. As the gravel in place reaches a depth of 185 feet, all of which shows gold, Mr. Larson expects to have it a paying hydraulic as well as a remunerative drift mine in a few years.

PLUMAS. **COMPLETED.**—*Plumas National*, Jan. 13: The Maxwell mining company have finally got the water through their new ditch and flume to Soda Bar. They have been at a vast expense and have labored long and well. We hope they will now reap the fruits of that labor, by finding that any amount of rich ground awaits their operation.

SIERRA.

GOLDEN STAR.—*Mountain Messenger*, Jan. 20: We are reliably informed that a channel has been found at last in the Golden Star claims below Allegheny. It will be recollected that William Hanley ran a long tunnel into the ridge but found nothing. He did not give up in despair, but came back within 800 feet of the mouth of the shaft zone, and there he found a ledge of 38 feet, found gravel which prospects well. It is cemented gravel and the gold is visible to the naked eye. It is further said that a tunnel to tap the channel will not necessarily be more than 800 or 1,000 feet long.

MICHIGAN.—The Michigan company have at last got their tunnel in and have tapped a body of paying gravel, and the prospects well. The company will now proceed to develop the mine as rapidly as possible. It is located between Newark and Gibsonville.

NORTH AMERICA.—The fine weather has enabled the lessees of the North America mine, whose buildings were recently burned, to get in a good supply of timbers, etc., enough to last them all winter, probably.

SWEEZEY. Parties are running a tunnel into the slide south of Klockner & Bro's old store at Port Wine, and believe they have a good thing.

DRY.—This is one of the driest winters ever experienced in this section. Port Wine, which usually has more water than many mining camps, is experiencing a water famine.

IOWA.—The company have their shaft down to gravel, but have not reached bedrock at last advice.

TUOLUMNE.

YANKEE HILL GRAVEL CLAIM.—*Tuolumne Independent*, Jan. 20: This claim, which was supposed to be worked out, is doing exceedingly well. A short time ago, Messrs. Brown and Johnson sold this ground to a San Francisco company. The first move was to put up a "giant"

hydraulic, which uses up some 500 inches of water. The work that has been done since, even with the scarcity of water, is wonderful—a cut at least 200 yards in length has been washed out over 80 feet deep and 200 feet wide. The superintendent, informed us that the claim, notwithstanding the heavy expenses it has been at to open it, has cleared itself (within \$300) in cash already taken out, and said if he had sufficient water to clean up the loose stuff already pried down, that he would not turn his hand over, but that he would clean up in three days \$8,000. The strata is of the character which miners term "bedrock," and is of the nature of coarse gold, while others have nothing but fine. The claim is down now over 80 feet, with "bedrock pitching" still. There are two channels on the right or west side, which Mr. Barron thinks eventually will come together. The ledge rises abruptly on the right, and close to its rise is the richest spot in this part of the claim, and is of a dirty olive green color, mixed with mill or country rock. At present there is not water enough to work to advantage, or to clean up what is down. From the outlook, it promises to be one of the best paying mines in this section of our country.

ITEMS.—*Union Democrat*, Jan. 20: The claim of Messrs. Brown, Macomber, Otis and Myers, at Caldwell's ranch, on Shaw's Flat, is doing well, and is showing a steady improvement. The Caldwell ranch diggings continue to increase in good pay at the rate of from 12 to 18 ounces per day, or \$5 per pan. The shafts on Shaw's Flat do not strike bedrock. The bedrock is apparent all over the Flat now. Messrs. J. Street & Co.'s new canal carrying water from the reservoirs (Phoenix) below the North fork of the Tuolumne, is in process of completion. Estimated cost, \$30,000. Fresh diggings have been made in the section with Sonora. The diggings paying well and the people are disputing as to whether the town is in Tuolumne or Stanislaus county. Another ditch company organized to carry water to Keeler's Ferry diggings on the Stanislaus river.

Nevada.

WASHOE DISTRICT.

CON. VIRGINIA.—*Gold Hill News*, Jan. 24: Daily yield, 235 tons of ore. The ore breasts going southward and eastward on the 1400-ft level are showing a steady improvement. The other ore-producing sections of the mine show little if any change. The enlargement of the drift connecting with the Gould & Curry mine on the 1550-ft level is going steadily forward, and is doing much toward affording the needed ventilation in that part of the mine. The west drift from the C. & C. shaft, on the 1650-ft level, out through the east wall and entered the ore vein during the first part of the week. According to measurements and calculations, made in accordance with the dip of the vein on the 1550-ft level, the ore was reached by a distance of 80 feet sooner than was expected. The dip of the vein at the point where it was struck is about 46°. The east wall is regular and perfect in its formation. The ore where it was first encountered gave assays ranging from \$30 to \$250 per ton. This drift is now in 23 feet, with every indication that the ore will prove richer with each foot that the drift is advanced. The appearance of the ore in this drift, when taken in connection with the solid and rich character of that found in the southeast drift from the deep winze in the California mine, gives an almost positive assurance that the 1650-ft level will prove equal, if not superior, to any level yet opened in the mine. No prospecting of this ledge has yet been attempted through the north drift on the 1700-ft level, the least being so great that such an attempt would be almost useless.

LEVATHAN.—The ore development mentioned last week has led additional encouragement and impulse to the work of opening up the resources of this mine at the 600-ft level. A fine streak of ore was cut through in the face of the north drift, and a cross-cut east was started to examine it. We visited the mine yesterday and found the cross-cut in a distance of 30 feet, with nearly the whole face in ore, some streaks of which give high assays. In fact, the whole assays from \$2 to \$30 to the ton. It is evidently an important development and very liable to lead to a good paying ore body.

CALIFORNIA.—Daily yield, 500 tons of ore, keeping all the mills steadily running. By prompt and active exertions the steady work of the mine has been cleared up, and the ore supply of the mills kept up, so that there is no apparent chance for any delay whatever in the crushing operations of the mine. The ore breasts on the 1400, 1500 and 1600-ft levels never looked more prosperous than at this time. In fact, the entire mine is looking far better than it did at the date of the payment of its first dividend. The south drift on the 1600-ft level is making steady progress, the face still in good ore. The main southeast drift from the deep winze on the 1650-ft level, is being pushed forward at as rapid a rate as the great heat will admit of, the full size of the drift still in rich ore. Sinking the C. & C. shaft is making slow progress, the flow of water at the bottom being fearfully strong.

BEST & BELCHER.—In cross-cut No. 1, on the 1700-ft level, the diamond drills have penetrated a distance of 305 feet, which, if we add the length of the drift—30 feet—would make a total of 335 feet prospected to the eastward. At that point the drills stuck, and their use had to be discontinued. A number of low assays were obtained from the drillings, but nothing that would seem to exhibit a prospect of a paying body of ore. The best of experts, however, coincide in the opinion that the drills have never yet penetrated far enough to the eastward to reach the ore vein now being opened upon in the Con. Virginia mine. The drills will now be placed in cross-cut No. 2, where the distance to the ledge is not supposed to be near as great as in cross-cut No. 1.

SILVER HILL.—The main incline has reached a point 100 feet perpendicularly below the 650-ft station, at which a new station is being opened preparatory to opening a new level.

CALEDONIA.—Sinking the main shaft has made fair progress during the week. The flow of water is still very strong. The 1350-ft level has been reached. The north drift on the 1150-ft level has completed a connection with the south drift from the Overman, securing a ventilation of the mine to that depth, and securing an escape of the workmen from either end in case of conflagration.

THE PROSPECTING drifts on both the 1300 and 1400-ft levels are steadily advancing with indications of the most favorable description. The flow of water is now easily handled by the new pumping machinery. The south drift on the 1200-ft level completed the connection with the Caledonia north drift yesterday, affording a long sought and much needed ventilation of the mine to that depth.

HALE & NORCROSS.—Everything at this mine is centered for the present in completing the reparation of the connecting drift with the Savage on the 1900-ft level.

JUSTICE.—Daily yield, 340 tons of ore, keeping the mills all steadily running. The ore breasts on the 500, 600 and 700-ft levels show no material change in either quality or yield of ore.

SURFLOUT.—The heavy flow of water from the shaft coming down through the roof of the tunnel being run beneath it from the ravine, renders the progress of drifting rather slow at present, but the water is rapidly draining out.

SIERRA NEVADA.—The north drifts on both the 1500 and 1700-ft levels are steadily advancing, the face of each showing a fine body of ore that will pay for milling. The prospects for ore in that portion of the mine are evidently growing better every day.

OHIO.—Sinking the main incline is being pushed forward with all the force that can be profitably employed in the prosecution of the work. Cross-cuts have been started on both the 1600 and 1700-ft levels to prospect the ledge. A small amount of ore is being extracted from the old workings on the 1500-ft level.

NORTH CON. VIRGINIA.—The heavy flow of water recently encountered at the 1100-ft level has been drained. The new pump station has been completed at the depth of 1150 feet. Sinking the main shaft will now be resumed. Diamond drills have been provided and are to be used in both the east and west drifts at the 1100-ft level in drawing off the water and assisting the progress of the drifts.

BALTIMORE AND AMERICAN FLAT.—Sinking the north winze below the 1050-ft level is making rapid headway, the vein of ore in the bottom still showing finely. The north drift on the same level is showing some good ore, affording rich assays.

DARDANELLES.—Under new and more favorable auspices a new working shaft has been started to open this mine at the proper point, and develop the merit of its lower depths to the best advantage. This is a first-class, three-compartment working shaft, and is being sunk about 400 feet southeast from the old shaft of the company.

BRONZE.—Daily yield, 130 tons of ore. The ore slopes show but little if any change. Sinking the main incline is considerably impeded by the flow of water. Opening the 1300-ft station in the combination drain shaft is being pushed with great vigor.

LADY WASHINGTON.—A lateral drift north from main east drift or cross-cut in 125 feet to-day; face in low grade ore. The winze from this drift is now down 30 feet, and is passing through very encouraging streaks of good vein material.

SOUTH COMSTOCK.—The lateral drift following the vein to the northward at the 300-ft level is now in 23 feet and the whole face in low grade ore.

MINT.—Sinking the main shaft is making excellent progress.

UTAH.—A fine large working station is being opened at the 1150-ft level, 750 feet below the 400-ft station, the last level opened and prospected in the mine. In the meantime another heavy lift pump is being put in at the 900-ft level, preparatory to starting the prospecting drifts at the 1150-ft level.

BECKEY.—The extraction of ore from the slopes north of the shaft on the 350-ft level is going forward as usual. The vein at that point varies from four to eight feet in width, and is proven to extend without interruption to the level above, a distance of 100 feet.

BULLION.—The south drift on the 1500-ft level is showing some fine quartz. The east drift on the 1000-ft level is to all app. arance just about ready to cut the ore vein at that point.

GOULD & CURRY.—The east drift on the 1700-ft level is again being driven forward. The winze below the 1700-ft level has been repaired, and is in good working order down to the 1800-ft level.

SAVAGE.—Everything is being done that is possible to complete the air communications with the Hale & Norcross, and as soon as that is done, draining the water below the 1900-ft level will be resumed.

CHOLLAR-FOTOS.—Sinking the main incline is making the usual fair rate of progress. Daily yield of ore, 100 tons, the assay value of which is \$39 per ton.

UNION COX.—Sinking the winze on the ore vein below the 1300-ft level is making excellent progress.

JULIA.—The south drift from the west cross-cut on the 1800-ft level is showing better every day as the drift advances.

MEXICAN.—Cross drifts for prospecting the ore vein are being started on both the 1000 and 1700-ft levels.

HOMESTEAD.—It will soon become necessary to erect machinery in order to expedite the sinking.

ALBUQUERQUE & ARGENTINA.—Shaft down 116 feet to-day. The entire bottom is in very promising vein material, some streaks of which give good assays.

CROWN POINT.—Sinking the main incline is making the best progress. The rock in the bottom blasts well, and the work is being forwarded with all the energy possible. The 2000-ft level will soon be reached at the present rate of speed.

YELLOW JACKET.—Sinking the new shaft is going steadily forward and is making the best of headway.

LADY BRYAN.—Nearly the whole of the new pumping machinery is in place ready for a trial trip.

FAIR GORE.—Face of main west drift still in porphyry, quartz and low grade ore, the quality of which, as indicated by assays, shows some little improvement.

SUCCESS.—The new pumping machinery is working splendidly and is keeping the water down.

KOSKUTI.—The south drift on the 600-ft level is steadily advancing, the face in very favorable ground.

FAIR TUNNEL.—Face of header continues to show hard porphyry, with occasional streaks of quartz and clay.

TOTAL LENGTH of tunnel this morning, 14,937 feet.

AMAZON & GLASGOW.—The north drift on the 400-ft level is being pushed vigorously forward, the face in quartz and ledge material of a very encouraging description.

PROSPECT.—West drift at the 400-ft level pushing ahead in ledge material with good streaks of quartz.

FLORIDA.—The shaft is now down 736 feet.

TROJAN.—The ore bodies on the 240 and 300-ft levels are opening up finely.

COSMOPOLITAN.—Face of north drift from bottom of winze continues in good ore.

SILVER CITY.—Excellent progress continues to be made in the development of the ore and bullion merits of the lower level, through the incline.

JETT DISTRICT.

NEW MINING FIELD.—The Belmont *Courier* publishes a lengthy descriptive account of the mines in Jett district, showing the amount of development, assays of ore extracted, etc. There are several mines opened in that district sufficiently to warrant an outlay of money in their further development. It is rumored that Jett & Davenport, the owners of the Idlewild, and discoverers of the district, are negotiating with parties for the sale of their interest. If the sale is effected, the purchasers will doubtless prosecute the work of opening up these mines more rapidly, and a new mining field of considerable importance will be added to this section of the State.

Arizona.

MINING NOTES.—*Wallapai Enterprise*, Jan. 13: Great activity is shown in the different camps throughout Turkey Creek district. In the Peck and Bradshaw districts a large force of men are at work—the Peck company alone employing over 40 men. The drift north from the level of the tunnel is in a distance of 100 feet, showing in places a body of very high grade ore, over three feet in width. The bottom of the main shaft, now down over 225 feet, shows a body of ore fully as large and equally rich. The amount of ore already in sight in this, the king of Arizona mines, is, in itself, a handsome stake for the lucky owners. The Black Warrior is producing some very rich ore, and the pay streak is growing as the work progresses. Stopping has been commenced, and ore is being taken out at a rapid rate and shipped by Dan Martin's pack train to the Agua Fria furnace. Work is being carried on, day and night, on the Silver Prince. Five tons of ore from this mine is now being treated at the Azilian mill. In the Bradshaw region, Jim Roach and others are at work on several claims owned by Luke & Co. The Idlewild has a fine body of gold-bearing quartz, over two feet wide, which will go over \$50 per ton. Several other parties are at work on their claims in this district. Mining throughout the Hassayampa and Groom Creek districts is brisk and active as ever. The Crook mill keeps pounding away, day and night, on ore from the Gen. Crook mine, with satisfactory results. Five stamps of Frederick's new mill have a fine body of gold and are working. Stopping has been commenced, and ore is being taken out at a rapid rate and shipped by Dan Martin's pack train to the Agua Fria furnace. Work is being carried on, day and night, on the Silver Prince. Five tons of ore from this mine is now being treated at the Azilian mill. In the Bradshaw region, Jim Roach and others are at work on several claims owned by Luke & Co. The Idlewild has a fine body of gold-bearing quartz, over two feet wide, which will go over \$50 per ton. Several other parties are at work on their claims in this district. Mining throughout the Hassayampa and Groom Creek districts is brisk and active as ever. The Crook mill keeps pounding away, day and night, on ore from the Gen. Crook mine, with satisfactory results. THE ENGINEER.

Turning Baths into Ice Factories.

It appears that our English friends succeed so well with their artificial skating rink (glaciarium) that they propose to freeze up their baths when the water becomes too cold for plunging. *Iron* says: Our readers will doubtless remember that on the 7th of last January skating was commenced on Mr. John Gamgee's first sheet of ice, 430 square feet in extent. A thousand square feet—the size of the glaciarium at Chelsea, which is still frozen—was the second attempt, and now 3,090 square feet of solid and transparent ice may be seen and used at the floating swimming baths on the Thames at Charing Cross. The floating baths were handed over to Mr. Gamgee on the 20th of October last, and within two months two complete sets of machinery, with all the accessories necessary for a glaciarium, have been satisfactorily erected. The general principles of the floating glaciarium consist of the circulation of a current of glycerine and water through a series of metal tubes immersed in water, which is converted into ice and maintained in that condition. The details, however, are different. These are two ice machines with the necessary engines, one at each end of the structure. Each machine absorbs over 100,000 heat-units per hour, and it is stated that this immense effect is obtained by utilizing about six-horse power per machine. The water of the Thames, at a temperature of about 40° or 42° Fah., pumped freely through the condenser, maintains the pressure in the machine at a minimum of one atmosphere and three-quarters, whereas the pressure in the refrigerator is only nominal, and corresponds to the temperature of about 0° Fah. A rotary pump drives about 4,000 gallons of glycerine and water per hour through each refrigerator, and this cold liquid traverses through the tubes of the glaciarium, and water outside them is thoroughly frozen. The special difficulties in maintaining congelation at the Charing Cross baths arise from the great radiation from the iron structure, which is caused by its immersion in the waters of the Thames and by the extensive area of glass roof covering the whole in, which greatly raises the temperature of the internal atmosphere, and is antagonistic to the development of artificial refrigeration. The desired result, however, has been attained, and ice two inches thick has been already formed, and skated upon, in the first instance, by two ladies. The machines act as twins. One supplies each alternate tube of 115 feet in length, and the glycerine, having passed through this, gravitates into the other machine, and, having been conducted through the refrigerator, passes back through the adjacent tube. In this way Mr. Gamgee secures what he terms his "direct alternative" circulation, which is the special improvement in the floating glaciarium. Each machine is capable of controlling the entire circuit of pipes, so that, in the event of one failing, the other insures the continuance of the process of congelation. It has been demonstrated, in fact, during the process of making the ice, that one machine is about sufficient to absorb the heat of radiation, which is exceptionally great in the floating structure. There is over a mile of wrought-iron flat tubing, which has been made under a very perfect system by the Metal Tube Company in the Euston road. The freezing machines have been constructed by Messrs. Raoul, Pietet & Co., the patentees of liquid sulphurous acid, with whom Mr. Gamgee is in co-operation. The general contractors for the works are Messrs. Emerson, Murgatroyd & Co., of Stockport. It is so arranged that when the bathing season again approaches, the ice machinery and apparatus will be taken down and stowed away, to be replaced for active use after the summer season.

Telegraph Engineers.

At a late meeting of the English Society of Telegraph Engineers, *Iron* says there was the usual extensive display of telegraphic instruments and other apparatus connected with telegraphy, but only one or two objects could be regarded as coming within the category of new inventions, and of these the most interesting appeared to be a new form of cable grapnel, exhibited by the Western and Brazilian Telegraph Company, and explained by Mr. A. Jamieson, who has for some years past been associated with the operations of foreign telegraph companies. Cable-lifting being an operation moved far beyond the sphere of ordinary observation, most people are ignorant of the peculiar difficulties by which it is surrounded. Of these, the breaking of grapnels is one of the most frequent and serious; and Mr. Jamieson's invention which is designed to overcome this difficulty, can hardly fail to prove a boon to foreign telegraph companies, of which so many have sprung into existence in recent years. The ordinary grapnel is furnished with rigid prongs, which, although perfectly well calculated to seize and bring a cable to the surface, are also liable to become fastened to rocks and other substances, and to break with the slightest strain of the ship. Of such frequent occurrence is this, indeed, that all cable ships are compelled to carry a very large stock of grapnels on board, and have often to return to port without accom-

plishing their task, owing to loss and breakage. Mr. Jamieson has furnished his grapnel with hinged prongs governed by a spring, which yields at a given strain, so that the moment a rock is "hooked" the grapnel slides off and comes to the surface. It is, in fact, an octopus-like machine, which puts forth its "feelers" in search of the real article, and draws them back the moment any counterfeit substance seeks to entangle them. This, with the new mariners' compass exhibited by Sir William Thomson, was perhaps the most interesting and valuable feature of the display made at Willis's rooms on Monday evening. The Society of Telegraph Engineers, which now numbers upwards of 800 members, was founded by Major Frank Bolton (the present water examiner of London), and Major C. E. Webber, of the Royal Engineers. The Society is in possession of the library bequeathed to it by the "father of telegraphy," the late Sir Francis Ronalds. This library (of which a catalogue is now being prepared), took Sir Francis Ronalds 40 years to get together, and it contains the finest collection of works on electricity to be found.

The Working of the Jetties.

New Orleans papers continue to bring evidence of the success of Captain Eads's engineering in the mouth of the Mississippi. The *Picayune* says: We learn that for some time past the channel between the jetties, at the South Pass, is everywhere more than 200 feet wide for a depth of 20 feet at average flood-tide, and that in the middle of this wide channel the depth is more than 22 feet. This is equal to from 22½ to 23 feet at the highest tide at South Pass, when a range of three feet tide, with a channel depth of 19½ feet, from 80 to 100 feet in width, is usually reported at Southwest Pass. Therefore it will be seen that the jetties have given, though yet in an incomplete state, a magnificent channel across the South Pass bar to sea, twice as wide and several feet deeper than has ever been obtained across the Southwest Pass bar. If this is considered as any indication of a failure of the jetty system, then we should welcome all such failures; they are what we should pray for earnestly. All through South Pass, from its head to the jettied channel over the bar, as is generally known, the depth exceeds 30 feet for more than 200 feet in width.

We are informed that the works required to confine the flow of water from the main river, above the common head of the passes, into South Pass, so as to secure a like deep channel entrance to South Pass over the river middle-ground shoal about its head, are being energetically prosecuted with every prospect of early success. Already, notwithstanding the low stage of the river, the one-dipper dredge boat at work there to expedite the cutting out of a deep channel entrance, has succeeded, as we are assured, in obtaining a depth of inlet of from 20 to 22 feet across this shoal, which the tidal current suffices to maintain and widen. Soon, we are told, two more powerful dredges will be put to work there and with three boats working together, an entrance channel across this hard sand middle-ground shoal, of sufficient width and depth for the largest class of ocean steamers, even at the present low river stage, may be expected at an early date. With the river at the height it was three months ago, we would have, even now, a clear and unobstructed channel of more than 22 feet in depth, from New Orleans to the sea, through South Pass.

REVERSING ENGINES.—There are now building in England for the Cleveland Steel Works a powerful pair of high-pressure reversing engines, on Ramsbotham's principle, being put down by Messrs. Thwaites & Carbutt, of the Vulcan iron works, Bradford. *Iron* says these engines are intended to drive the ingot cogging mill trains, and are placed parallel to each other on massive cast iron beds, whose weakest point is one foot nine inches deep, and the strongest (viz., the gearing end) three feet three inches deep. The diameter of the cylinder is 36 inches, and the stroke four feet six inches. The centers of the beds are 12 feet apart, and the total area which they occupy is 43 feet long by 17 feet wide. The engine beds are truly planed, so as to have a thorough bearing upon the foundation, the top of which is composed of ashlar stones, three feet thick, below which there is a solid mass of concrete, 19 feet deep, and they are held down upon this foundation with 24 three-inch bolts, 25 feet long. The crank shaft, second motion shaft, piston rods and crank pins are all of Krupp's steel. The cranks are wrought iron, and have solid balance weights opposite the cranks. The connecting rods are also of wrought iron, nine inches diameter in the center; the gearing is in the ratio of three to one. The large wheel, which weighs 20 tons, is 12 feet eight and seven-eighths inches diameter, and has eight-inch pitch and 20 inches breadth of tooth. The steam valves are pistons packed with simple cast iron rings. The steam ports are very short to save steam, and the exhaust ports very large to maintain a free exhaust. The total weight of the engine will be 130 tons, and it can be reversed up to as many as 60 times per minute with great ease by one man. The makers of this engine are also supplying six powerful double-ended rail straightening machines, each of which is furnished with a self-contained engine, so that it can be worked independently.

Prospects in Eureka.

The presence of a number of the mining magnates from San Francisco in our midst for the past few days has caused considerable curiosity to be evinced by all parties. The rumors current for a week past of extensive bodies of ore being discovered in three different mines on Ruby hill, are now generally conceded to be true, and those in a position to give accurate information do not deny but what the developments brought to light within the past few days have been of a nature entirely satisfactory to the stockholders of the mines referred to.

The discovery of a large body of high grade ore in the Eureka Consolidated, and the well sustained raise in the value of the stock at the rate of two dollars a day, is the subject of general congratulation among the citizens of Eureka, who recognize the fact that it is the herald of better times for our town. The company has always dealt justly and liberally with its employees and the business men, and the mine itself is identified with our prosperity. The discovery of an ore body on the lower levels, and its contiguity to the Richmond settles effectually the problem of permanence to the vein and the importance of deep working. The Base range has suffered more from ill-digested theories of scientific sharps than any mining region, and, like the Comstock, we have had to work out our own salvation. Nature has done a great deal for us, and pluck and perseverance a great deal more, and those who have had the faith to cast their fortunes with us will reap a rich reward. As to the extent or value of the discovery time alone can tell. We do not imagine that the president or superintendent will reveal it; mines are not managed in that way, but the most casual observer can note the signs and draw his own conclusions, and the community have made up their minds that there is good grounds for the belief and rejoice accordingly. The presence of the president, General Dodge, and that irrepressible mining sharp, J. Corrigan, the arrival of ex-president J. Zeile and John W. Shaw, and the general good humor of the party is very significant. Under the intelligent management of Superintendent Donnelly the mine will yet rank as one of the great mining properties of Nevada.

The K. K. is also coming in for its share of attention, showing in return the largest and finest body of ore ever discovered in the mine. The latest developments were made on the fourth level near the top or cone of the ore body. A winze is being sunk on the same, and Superintendent Arrington, writing to the directors in San Francisco, says: "I have the greatest faith in this strike proving a valuable discovery. No estimate can be made of the actual extent of the bodies of ore discovered, but enough has been ascertained to know that to-day the K. K. possesses a body of ore second to none of its neighbors."

Reports of a similar strike in the Jackson are circulated on the street. No definite information as to the reported discoveries, or of the character of ore found, is given.—*Eureka Sentinel*.

Mining in Arizona.

The arrival in Los Angeles of Col. James M. Barney, of Yuma, and Mr. Mason, has given the *Los Angeles Herald* an opportunity for a very interesting conversation on Arizona and her prospective mining development. Col. Barney is understood to have purchased from Mr. Mason a half interest in the famous Silver King mine for \$300,000. He describes that mine as very rich, and says that if it proves to be of a permanent character it will surpass the bonanza mines themselves. Of course its durability can only be ascertained by time, as it cannot as yet be said to have been even prospected, the trifling depth—short of 150 feet—to which it has been pushed, being a mere "starter." Should the lode hold out in its present richness to great depths, it would eclipse all recorded mines in its outcome, except such as are described in the fables of early mining development of Mexico and Peru. We have heretofore described the location of this mine in the Pinal mountains.

The owners of the Silver King mine are at present only shipping to San Francisco ores which average \$1,000 to the ton. Seventy-five or 100 tons of this rich rock are now en route to San Francisco, via the steamers of the Colorado River Navigation Company. It costs to haul the ore to the Colorado river from the mine \$65 a ton. The steamers transport it to San Francisco for \$10, as they are glad to get it for ballast. They carry ore from Ehrenberg for \$15 per ton.

Colonel Barney informs us that mining in all sections of Arizona has received a decided impetus of late, and that the prospectors are pouring in there in great numbers. The Territory shows this activity in every direction, about Tucson, Prescott and up in the Mohave country. The greatest animation, however, is observable in the Globe district, where a great number of claims have been taken up, and where the indications are certainly very promising.

The completion of the railway to Yuma will shortly stimulate every kind of development, and will make that town a very lively place. It will probably benefit by a large Mexican trade. While the railroad company in all likelihood cannot afford to carry ores to San Francisco any cheaper than the Colorado Steam Navigation Company, there will result a marked benefit to the miners in the expedition with which their

ores can be transported to the reduction works at San Francisco by the railroad. Now, if the teams miss the steamers, the ore shipments have to wait 30 or 40 days for the next steamer.

For the last three or four years Col. Barney has shipped 100 or so tons of Castle Dome ore to San Francisco monthly. The Castle Dome rock is a lead ore, for which the San Francisco smelters pay about \$60 a ton. They work it with the rich Silver King ore to decided advantage. The Castle Dome ore goes about \$30 to the ton in silver, and averages 75% in lead. By a combination of the two ores the "flux" is readily obtained and the greatest possible percentage of profit is thus secured.

It is our informant's opinion that reduction works will shortly be established in this southern country, possibly at Los Angeles, but probably at some point in Arizona, thus dispensing with the expensive carriage of ores. There is abundance of fuel for this purpose within easy reach of the mines.

Col. Barney confirmed Mr. Pomroy's statements about the Globe and other districts relying upon New Mexico for supplies. He says that the loss to California of the trade of those camps will be repaired measurably by the completion of a wagon road from the mines to Yuma, a distance of 245 miles. This road will be finished shortly. In reply to a question as to whether Arizona would not depend largely on Los Angeles county for produce of various kinds, Colonel Barney said that the people of the Territory were amply capable of raising all the vegetables and cereals that would be consumed by them. Of course, our wines, brandies and semi-tropical fruits will have full swing, and there is no reason why our commercial relations with Arizona should not be indefinitely expanded.

The deepest mine which has thus far been sunk in Arizona is the Vulture, and that is only down to a depth of 300 or 400 feet. A development is now going on which will test the vexed question as to whether or not the Territory is as rich, minerally, as Nevada. As Arizona is an important portion of the "back country" of Los Angeles, we trust the question will be decided in the affirmative, and from the complexion of the reports which reach us from that quarter we believe it will. Miners are now rushing there from Colorado, Utah, California and Nevada, and the result of this experiment cannot be long in coming to our ears.

Southern Humboldt.

Two individuals, one of them a representative of the *Silver State*, boarded a freight train at the depot, last Friday night, and were landed before midnight at

Mill City.

The shipping station for Unionville, Star, Dun Glen and Central mining districts. In early days, Mill City was selected as the terminus of the Humboldt canal, which was to convey water taken from the river 40 miles above to run a number of prospective quartz mills, hence the name. It boasts of a good hotel, a freight house, several dwellings and out-houses and a first-class foundry, where anything in the line of castings is turned out to order on the shortest notice. George M. Miller runs a daily stage between this point and Unionville, carrying passengers, mails and Wells, Fargo & Co.'s express. Twelve miles south on the road to Unionville is

Star City.

In 1863 the most populous and prominent mining camp in the county. At present there are but few mining enterprises carried on in the district, the principal one being the Sheba, on which there are hoisting works and an Ingersoll drill, run by water. The drill, which has just been put in place in the mine, makes 200 revolutions a minute and bores a hole two or more inches in diameter, and 12 inches deep, in solid quartz, in six minutes. The drill is run by compressed air, but water is the power used in compressing the air, and a stream of that liquid which, under pressure, is not more than an inch in diameter, runs the hoisting works and drill. The mine is producing some very rich ore, but at present it is limited in quantity.

Eight miles south of Star is

Unionville.

The most extensive and prosperous mining camp in the county. The ruinous discount on bullion during the last year, which discouraged prospecting and retarded the development of mines in all parts of the State outside of the Comstock, has seriously affected Unionville, and at present the only mine worked is the

Arizona.

Which, under the management of J. C. Fall, withstood the pressure to which other mining enterprises succumbed and is now looking and paying better than at any time during the last year and a half. Two of the four mills in the place are running steadily on Arizona ore. To supply these mills with fuel, six six-mule teams are constantly employed in hauling sage brush. The brush is chopped and gathered in winrows by Indians and Chinese, who work in separate gangs, and between whom there is a considerable rivalry in the business. A large pile of cedar and nut-pine wood is held in reserve near the mills, to supply them in the event of accident or delay to the brush teams. The valley for miles in every direction from the mills is denuded of brush, and the bare circle is being daily enlarged. Everybody in Unionville is at work.—*Silver State*.

Kern County Mines.

Erskine Creek.

The Kern County *Courier*, in a series of articles on the interests of the county, says: The Erskine creek mines are on a creek of that name that in the spring pays tribute to Kern river, some eight or ten miles below Kernville, running through Hot Spring valley. Several rich leads have been found on this creek and some work has been done, but, although the rock is so extraordinarily rich, assaying as high as \$700 in gold to the ton, but little else than prospecting has been done. The holders have been somewhat embarrassed and unable to prosecute operations successfully. A short time since, however, these mines, consisting of several locations, all under one management, have passed into the hands of enterprising parties in San Francisco, who have the means and disposition to place this property in productive condition. They are now perfecting arrangements to that end, moving their mill, opening their mines, etc., and in a short time we may expect to see another prosperous settlement on Erskine creek, that will probably dispute the honor of supremacy with both Kernville and Bull Run.

Piute and Sageland, situated in the same range, are both good mining camps. The Bright Star at Piute, and the St. John at Sageland, have yielded largely of the precious metals, and will, if properly worked, continue to do so. Northwest, and on the western slope of the great Sierra, and in the foothills, the Long Tom mines are located. They have been very profitably worked, and large amounts extracted from them. At present there is not much doing, owing to mismanagement and litigation. They are universally recognized as valuable, and much impatience is manifested at the policy that prevents their operation. If the difficulties were removed, probably 150 persons would find profitable employment.

In the southern enclosure of the great valley, in what are called the San Emidio mountains, where the Sierra Nevada and Coast Range meet and merge into the Sierra Madre, is a region of which comparatively little is known, other than that it is rich in various minerals. Rich gold placers have been found and worked in Lockwood valley, on the Piru creek and its tributaries, the scarcity of sufficient water for washing purposes during the greater portion of the year being the only drawback. Valuable deposits of tin, antimony, silver-bearing galena and gold-bearing quartz have been found. Boushay & Co., of Los Angeles, have erected works, and are now successfully working the antimony mines. Another Los Angeles firm, Eggleston & Co., are erecting a mill at the Frazier mine. This is a quartz mine which has been extensively prospected with arrastras, by which process it yields an average of \$60 per ton in free gold. A well authenticated tradition exists that a very valuable silver mine was found in these mountains and worked by the Indians under the direction of the Mexican padres long before the American occupation of the country. The crafty padres, however, kept the location a profound secret, which it remains to this day, notwithstanding much search has been expended in the endeavor to recover the lost mine. The valuable church plate of the mission of San Luis Obispo was brought from this place. The remains of the old furnaces employed for reducing the ores have been found, but all efforts to discover the mines have proven futile. The surface of this part of the country is exceedingly rough, lofty and inaccessible mountains and precipitous and impenetrable chasms impeding the progress of the explorer at every turn. Still, enough is known about it to warrant the assertion that it would richly repay the adventurous prospector, and the time is not far distant when it will team with a prosperous population and yield abundant returns of mineral wealth. Further west, in the extreme southwestern corner of the county, are the Buena Vista petroleum works. They were erected some years ago by a Mariposa company, but for some reason the enterprise was suspended and still remains so. Great quantities of asphaltum and oil are constantly oozing from the earth and flowing away; the oil being very volatile soon evaporates, leaving the dry, hard residuum on the ground. At several other places in the valley and the foothills there are oil springs of the same character. One has been discovered in the bed of Kern river a few miles above Bakersfield. It discharges into the river, where the oil may be seen floating on the water. Operations are about to be commenced on this spring to find the reservoir that is believed to exist. Now that the railroad reaches within 40 miles of the Buena Vista oil works, it is believed that they could be worked with large profit to the company. The mountains are also rich in vast deposits of gypsum, marble, limestone and slate of the finest quality, which will shortly become valuable commercial products. East of the Sierras are great fields of borax, which have been worked to some extent. A large home consumption will be found for this product as the mines of the country become developed, especially in Inyo county, where as an auxiliary in fluxing the galena ores of that section it will be greatly needed.

AN IMPROVEMENT IN THE FILTER PUMP.—Dr. Walker Hempel, of Germany, suggests, as a means of quickening the action of the filter pump, that a series of five radial lines be etched in the funnel, below the top of the filter to the neck. By this system of little canals the action of the apparatus is claimed to be considerably accelerated.

USEFUL INFORMATION.

Seasoned Timber May Shrink.

The *Manufacturer and Builder* says: Scraping off the paint from a panel in a door will cause it to shrink, even when it has been unaltered for years, and supposed to be perfectly seasoned. Even the various most valuable kinds of timber will shrink more or less every time the surface is dressed off even a small fraction of an inch. Wheelwrights, accustomed to work in oak, are well aware of this fact, and a correct appreciation of it often enables them to turn out work of a superior character, even of ordinary materials, by first blocking out the pieces roughly, then allowing the timber to season, and working the various parts by degrees, as the seasoning becomes more and more complete.

White oak spoke timber, for example, may be allowed to remain in a rough state for half a score of years, under shelter, without becoming seasoned so thoroughly that the timber will not shrink after the spokes have been dressed out. Carriage wheels have often been made of the choicest quality of oak timber after every spoke has been seasoned for several years, and to the great surprise of the wheelwright, every spoke would work in the joints before the vehicle had run three months. The defect in such instances could not be attributed to inferior timber, nor to perfunctory workmanship, but simply to this one circumstance, that the parts of the wheel were put together before the timber had ceased to shrink.

To prove that the best quality of oak will shrink after a spoke has been dressed out, let a tenon be made on one end and be driven immediately into a mortise; after a few days' exposure in a warm workshop the spokes may be withdrawn with little difficulty. The same fact will hold good in the manufacture of wood work of any kind where oak is employed for tenons. In order to make joints that will never start, the piece on which the tenons are to be made should be dressed several times, until the shrinkage has ceased; then let the tenons be made. After these have shrunk, while exposed to the drying influence of a warm workshop, the spokes or other parts may be driven into their respective places, with the assurance (especially if they are dipped in oil paint previous to driving) that timber will shrink no more.

Many kinds of farming implements, in the manufacture of which oak and ash are employed, render very unsatisfactory service, simply because the seasoned timbers were not allowed to shrink before the tenons were driven into the mortises. In like manner, oak chairs and other furniture will frequently shrink to such an extent that the pommels, rungs, dowels, pin and banisters will all work loose if the precaution we have described is not observed.

IRON OF ANTIQUITY.—The oldest pieces of iron (wrought iron) now known are probably the sickle blade found by Belzoni under the base of a sphinx at Karnac, near Thebes; the blade found by Col. Vyse embedded in the masonry of the great pyramid; the portion of a cross-cut saw exhumed at Nimrod by Mr. Layard, all of which are now in the British Museum. A wrought bar of Damascus steel was presented by King Porus to Alexander the Great, and the razor steel of China for many centuries has surpassed all European steel in temper and durability of edge. The Hindoos appear to have made wrought iron directly from the ore, without passing it through the furnace; from time immemorial, and elaborately wrought masses of iron are still found in India, which date from the early centuries of the Christian era.

UTILIZATION OF SAWDUST.—Sawdust can be converted into a pasty state, and afterwards into a solid, flexible, and almost indestructible mass, which when incorporated with animal matter, rolled, and dried, can be used for the most delicate impressions, as well as for the formation of solid durable articles, in the following manner: immerse the dust of any kind of wood in diluted sulphuric acid, sufficiently strong to affect the fibers, for some days; the finer parts are then passed through a sieve, well stirred, and allowed to settle. Drain the liquid from the sediment, and mix the latter with a proportionate quantity of animal offal, similar to that used for glue. Roll the mass, pack it in molds, and allow it to dry.

LIQUID WHICH WILL STAND HEAT AND COLD.—It is often necessary to surround the pipes of heating or evaporating apparatus, and hot-air apparatus, ovens, stoves, etc., with a liquid which will not boil at a temperature of 212° F.; it is also often necessary to make use of baths which will not easily boil or freeze. The liquids usually employed for this purpose are water in which sea salt has been dissolved, oil baths, etc. Instead of these various agents, it is now proposed to make a solution of chloride of lime in glycerine, a solution which does not boil below 572° or 626° F., and has the further advantages of never attacking metals nor congealing.

SIZE OF WAGON WHEELS.—Experiments made many years ago on the European continent, and recently repeated in England, verify practically the conclusion which a common sense mechanical theory suggests, that wagons are most easily drawn, on all kinds of roads, when the fore and hind wheels are of the same size, and when the pole lies slightly lower than the axle.

COLORING CEMENT FIT FOR GRINDING AND POLISHING.—Colored cements are used to give cast goods of zinc or brass the appearance of burlwork, and to fill up the holes made by etching in zinc door-plates, street numbers, coats of arms, etc. They are also, with advantage, employed for making casting-models of more artistic objects, as well as for mosaics on metal ground; but they may be further found useful in engineering works for isolators, large rings and plates. According to Stach, the following procedure is necessary in their preparation: A solution of soluble glass of 33° Beau, is mixed with fine whitening, with the addition of the materials mentioned below, until it assumes the tenacity of a thick plastic mass, and thus different colored cements, hardening in six or seven hours, of considerable strength, and very useful for the purposes above quoted, are obtained. By adding gray sulphuret of antimony a black cement is obtained; this may be polished with agate, and has a metallic onyx-like luster. Another black cement is prepared by mixing equal parts of sulphuret of antimony and iron filings (finest) with the above soluble glass; but the cement can only be ground. Carbonate of copper, pure chrome green, green; cobalt blue, blue cements. (Ordinary ultramarine is not fit for use, because it forms Glauber's salt and scatters the mass.) Red lead gives orange cement, sulphide of cadmium citrine, cinnabar bright red and cochineal-lac violet cement; zinc dust and alcoholized iron give a brown cement and powdered manganese acts in the same manner. An especially valuable gray cement, which may be polished with the agate to a metallic luster, and used in the repair of damaged zinc ornaments—whether cast or of sheet zinc—is produced by mixing pure most finely-sifted zinc dust with soluble glass. Hitherto these mixtures have been used solely for imitating marble, but the cements are also of great value in the metal-ware industry.

PAINTING GILT PAPER.—We wished to paint, with water colors, a monogram on gilt paper, but could not get the paint to lie, not even when mixed with gum; it either scaled off, or was patchy. After trying various expedients, we scratched all over the surface of the monogram with a hard lead pencil, and we then found that the water colors could be easily painted on the surface. Their effect on the gold ground was very great, and perhaps some of our "illuminating" readers may thank us for illuminating them with this "wrinkle."—*Printers' Register*.

GOOD HEALTH.

Curiosities of Eating.

An old beau, formerly well known in Washington City, was accustomed to eat but one meal in 24 hours; if after this he had to go to a party and take a second dinner, he ate nothing all the next day. He died at the age of 70.

A lady of culture, refinement and unusual powers of observation and comparison, became a widow. Reduced from affluence to poverty, with a large family of small children dependent on her manual labor for daily food, she made a variety of experiments to ascertain what articles could be purchased for the least money, and would at the same time "go the furthest," by keeping her children longest from crying for something to eat. She soon discovered that when they ate buckwheat cakes and molasses they were quiet for a longer time than after eating any other kind of food.

A distinguished judge of the United States Court observed that when he took buckwheat cakes for breakfast, he could sit on the bench the whole day without being uncomfortably hungry; if the cakes were omitted, he felt obliged to take a lunch about noon. Buckwheat cakes are a universal favorite at the winter breakfast table, and scientific investigation and analysis has shown that they abound in the heat-forming principle; hence nature takes away our appetite for them in summer.

During the Irish famine, when many died of hunger, the poor were often found spending their last shilling for tea, tobacco and spirits. It has also been observed in New York, by those connected with charitable institutions, that when money was paid to the poor, they often laid it all out in tea or coffee, instead of procuring more substantial food, such as meal, flour and potatoes.

On being reproved for their apparent extravagance, the universal cry was in both cases identical; their own observation had shown them that a penny's worth of tea, tobacco or liquor would keep off the sense of hunger longer than a penny's worth of anything else. Scientific men express the idea by saying: "Tea, like alcohol, retards the metamorphose of the tissues; in other words, it gives fuel to the flame of life, and thus prevents it from consuming the fat and flesh of the body."

If a person gets into the habit of taking a lunch between breakfast and dinner, he will soon find himself getting rather faint about the regular luncheon time; but let him be so pressed with important engagements for several days in succession as to take nothing between meals, and it will not be long before he can dispense with his lunch altogether. These things seem to show that, to a certain extent, eating is a mere habit. Whole tribes of Indians, hunters and trappers have been known to eat but once in 24 hours and that at night.—*Hall's Journal of Health*.

Do Not Face the Light When at Work.

Statistics kept by oculists employed in infirmaries for eye diseases, says the *Builder*, have shown that the habit of some persons in facing a window from which the light falls directly in the eyes as well as on the work, injures their eyes in the end. The best way is to work with a side light, or, if the work needs a strong illumination, so that it is necessary to have the working table before the window, the lower portion of the latter should be covered with a screen, so as to have a top light alone, which does not shine in the eyes when the head is slightly bent over and downward toward the work.

In the schools in Germany this matter has already been attended to, and the rule adopted to have all the seats and tables so arranged that the pupils never face the windows, but only have side lights from the left; and as a light simultaneously thrown from two sides gives an interference of shadows, it has been strictly forbidden to build school-rooms with windows on both sides, such illumination having also been proved to be injurious to the eyes of the pupils.

We may add to this the advice not to place the lamp in front of you when at work in the evening, but a little to one side; and never to neglect the use of a shade, so as to prevent the strong light shining in the eyes. This is especially to be considered at the present time, when the use of kerosene lamps, with their intensely luminous flames, becomes more and more common.

CARBOLIC ACID IN DIPHTHERIA.—W. H. Kempster, one of the health officers of London, writes to the *Lancet* as follows: "On reading Dr. George Johnson's admirable paper on diphtheria in your late issues, in which he advocates local disinfectants in the treatment of that disease, I was surprised to observe that while he recommends the use of chlorine, permanganate of potash, sulphurous acid, and more especially perchloride of iron, no mention is made of carbolic acid—an agent tried by me some years ago in despair at the almost invariably fatal termination of cases treated by the agents recommended by Dr. Johnson. Since that time, by using carbolic acid, given in the form of a mixture of *Acid. Carbolic. Opt.* (Calvert's), one to five minims (according to age), with a drachm or two of syrup of orange and water (thus getting rid of gargles and the painful operation of swabbing the throat, the act of deglutition bringing the medicament into contact with the fauces and other parts affected), I have lost but one patient out of some 30 or 40, in which case the air passages were affected from the first. It is well to state that in all these cases the characteristic exudation was visible, and they were not cases of ordinary croup." Mr. Kempster writes at a later date, that numerous cases since treated on the above plan have all recovered; in very severe cases he obtains good results by local application of No. 1 carbolic and glycerine (1 to 4) with a camel-hair brush.

HOT WATER FOR INJURIES AND BRUISES.—The New York *Medical Journal* reports this case: The patient was engaged in a machine shop, and while his hand was upon the anvil of a trip-hammer, the hammer—weighing 700 lbs.—fell. It so happened that a file was on the anvil, and in this way the force of the hammer was arrested about half an inch before it reached the bed. When the hand was examined it was found that the whole palm was a mass of pulp. The metacarpal bones were comminuted extensively, and there was, apparently, but small chance of saving the hand. It was, however, placed in hot water, and kept there for two or three weeks, and then taken out and dressed. In three months the patient was sufficiently well to leave the hospital, and now—nine months after the accident—he is able to move the fingers and has quite a useful hand. Bruises and injuries do much better when treated with hot than with cold water. The temperature should be about 103° Fahrenheit. Another case is reported of compound fracture and discoloration of the ankle joint, in which the proximal end of the first metatarsal bone protruded from the foot. The dislocation was reduced and the foot placed in hot water. At the end of a week it was taken out and dressed in the ordinary manner. The foot is now doing well and promises a good return.

HYGIENIC INFLUENCE OF COMPRESSED AIR.—It has been supposed by some that the effects of compressed air on workmen were injurious, but Siebe, an eminent German hydraulic engineer, has established, by a series of experiments during several years, the fact that workmen working in caissons, attain, in a short time, a remarkable degree of comfort; and that their chests become strengthened to a remarkable degree. He has also ascertained that pulmonary complaints become cured by thus working under water. In consequence of this, Dr. Carlo Farinacci, of Milan, has established an erotherapeutic establishment, for the treatment of pulmonary complaints.—*Revue Industrielle*.

SIMPLE REMEDY TO STOP BLEEDING.—Mr. F. E. Forster cut himself, and trying to stop bleeding, he did not succeed, notwithstanding he tried to do it in several ways; finally the idea struck him to put on some dry plaster of paris, which happened to be at hand. It stopped the bleeding at once, while it only caused some stinging sensation, lasting a minute or two, but no ill effects were experienced.

Advertising Rates.	1 week.	1 month.	3 mos.	12 mos.
Per line.	.25	.80	\$ 2.00	\$ 5.00
Half inch (1 square).	\$1.00	\$3.00	7.50	24.00
One inch.	1.50	4.00	12.00	40.00

Four weeks are rated as one month.
Large advertisements at favorable rates. Special or
reading notices, legal advertisements, notices appearing
in extraordinary type or in particular parts of the paper
inserted at special rates.

SUBSCRIPTION IN ADVANCE—Postage paid—one year, \$4;
six months, \$2.25; three months, \$1.25. Remittances by
registered letters or P. O. orders at our risk.

SAMPLE COPIES.—Occasionally we send copies of this
paper to persons who we believe would be benefited by
receiving it, or willing to assist us in extending its
circulation. We call the attention of such to our pros-
pectus and terms of subscription.

THE ORIGINAL ARTICLES in this paper are mostly set in
solid type, giving in our columns one-third more reading
than is contained in ordinary leaded matter.

ADDRESS all letters to the firm, and not to individual
members, or others, who may at any time be absent.

Our latest forms go to press on Thursday evening.

SAN FRANCISCO:

Saturday Morning, Jan. 27, 1877.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Compound Steam
Pump; American Miners; Copper; 43. Mining
and Farming Ground; California State Geological So-
ciety; Mining Stocks, 58. Comstock Papers, No. 14;
Mechanical Ore Concentration, No. 19, 57. Patents
and Inventions; Notices of Recent Patents; Raymond
& Ely Mine, 60.

ILLUSTRATIONS.—Walker's Compound Steam
Pump; Sectional View of Walker's Compound Steam
Pump, 49. Revolving Wet Double Screens, 57.

CORRESPONDENCE.—Mining in Deer Lodge
County, Montana, 50.

SCIENTIFIC PROGRESS.—Light and the Eyes;
Chemistry in America; Making Fabrics Unflammable;
The Diamond Drill in English Geology; Mica Scale
Pans; Buried Forests, 51.

MECHANICAL PROGRESS.—Sand in Irons. The
Locomotive at Sea; Using Putty; Hoisting Apparatus
and Stamp Hammer, 51.

MINING SUMMARY from the counties in Cali-
fornia, Nevada, Utah, Arizona and Idaho, 53-60.

THE ENGINEER.—Turning Baths into Ice Factories;
Telegraph Engineers; The Working of the Jetties; Re-
versing Engines, 54.

USEFUL INFORMATION.—Seasoned Timber
May Shrink; Iron of Antiquity; Utilization of Sawdust;
Liquid which will Stand Heat and Cold; Size of Wagon
Wheels; Colored Cement Fit for Grinding and Polishing;
Painting Gilt Paper, 55.

GOOD HEALTH.—Curiosities of Eating; Do Not
Face the Light When at Work; Carbolic Acid in Dipht-
heria; Hot Water for Injuries and Bruises; Hygienic
Influence of Compressed Air; Simple Remedy to Stop
Bleeding, 55.

GENERAL NEWS ITEMS on page 61 and other
pages.
MISCELLANEOUS.—Underground Condition of the
California Mine, 50. Prospects in Eureka; Mining in
Arizona; Southern Humboldt, 54. Kern County
Mines; An Improvement in the Filter Pump, 55.
Base Bullion, 58. The Mariposa Estate, 58-59. Suc-
cessful Working; El Paso District; Smelting, 59. New
Incorporations; Items of Interest from the Mines; The
Knickerbocker Mining Company, 60. Black Hills
Items, 60, 61.

NEW ADVERTISEMENTS.

Pickering Engine Governor, Neylan & Young, S. F.; Pa-
cific Iron Works, Rankin, Brayton & Co., S. F.; Web-
ster's Dictionary, G. M. Merriam, Springfield, Mass.

CALIFORNIA INSURANCE COMPANY.—The an-
nual statement of the California Insurance
Company shows the capital stock, \$300,000, to
be all paid up. The total assets are \$560,704.39,
and the liabilities \$100,206.39, the surplus as
regards the policy holders being \$160,498.03.
During the year fire losses to the amount of
\$27,452.85, and marine losses to the amount of
\$37,283.59, were incurred.

BULLION.—The leading producing mines
produced the following amounts in December:
Belcher, \$112,000; California, \$128,211;
Chollar-Potosi, \$63,971; Consolidated Virginia,
\$351,717; Justice, \$276,497; K. K. Con-
solidated, \$55,000; Leopard, \$66,000; Manhattan,
\$90,500; Modoc, \$93,570; Northern Belle,
\$171,748; Ontario, \$30,000; Ophir, \$60,000;
Tybo Consolidated, 68,300. Total, \$2,732,514.

The Miners' Association of Cornwall and Devon
have classes for the purpose of teaching var-
ious branches of science, and have decided to
have a medal struck, to be awarded to the stu-
dents who distinguish themselves in those
classes. The young miner must have worked
underground twelve months previously before he
is entitled to the medal.

The Nevada bank has loaned \$600,000 to Al-
vinza Hayward and \$300,000 to Milton S. La-
tham, at nine per cent. per annum.

LEAD in Liverpool on January 1st was £21 15s
@22 5s for good ordinary brands, and £21 @21 5s
for Spanish soft silver.

THE Empire mining company of Grass Valley
shipped bullion for November account, \$13,682.
62, and for December account, \$15,130.96.

Mining and Farming Ground.

In many places in the foothills of this State,
where mining was carried on in early days, and
the ground turned over and over in search for
gold, it is again made to yield wealth in the
shape of agricultural products. It used to be
supposed that ground once disturbed by mining
entirely lost its usefulness for other purposes,
but time and experience have proved the fallacy
of the idea. Hundreds of instances might be
cited where old mining ground has been turned
into farms. Districts formerly giving support
to miners alone, now, in many cases, have a pop-
ulation almost entirely agricultural in its char-
acter. The foothills of California, long consid-
ered worthless for anything, furnish the best
fruit in the markets, and the "red lands" prove
their value by yielding as abundant crops of cer-
tain products as the apparently richer lands of
the valleys.

In some parts of the State the owners of the
land get both mineral and agricultural products
from the same tract, working sometimes as
miners and sometimes as farmers. Of course
this is not general, but the fact may be cited as
showing the wealth of certain districts. It is
also a refutation of the charge against miners
that they utterly destroy the land on which
they work, and, unlike the farmers, get only
one "crop." In fact, a large portion of the
placer ground in California has been worked
over two or three times, and a good deal is now
being worked again by Chinamen, who make a
fair living by it. It has also been found that
underlying the placers of early days, long since
worked out, in many places lies ground nearly
as rich, but covered by a capping of rock, under
which the miner must work to get out the au-
riferous gravel deposited there ages ago.

We used to think that when the placers were
gone mining was nearly done for. Then we
found the gravel or hydraulic mines, a branch of
industry which, although now large in extent,
is growing from year to year, and which will
continue to be prosecuted by future generations.
Immense hills of gravel, acres and acres in ex-
tent, still lie untouched in the mining regions of
California, waiting patiently their turn to be
swept into valleys, yielding their golden metals
in the process. A large part of that ground
will even then be in a condition to yield support
to our people, though in a different way from
what it does now. The farmer will plow, sow
and reap where the miner has blasted, washed
and cleaned up, and the ground which has
yielded its stored-up mineral treasures will, in
process of time, develop agricultural riches as
well.

But nothing except the immediate future can
greatly interest the present owners; few of them
are planting acorns for future oaks, but are get-
ting what the ground will produce in as rapid a
manner as possible, in accordance with the uni-
versal California theory and practice. The peo-
ple referred to previously, who can mine and
farm both, consider themselves lucky in making
the land yield in more than one way; for if a
man can grow fruit over a substratum of gold
he can afford to let a part of his land lie fallow
on the surface each year while he strips it from
below. Only this week we noted in the Cala-
veras Chronicle that a Mr. J. R. Strange, who
some time since discovered an immensely rich
stratum of gravel in his lot in the suburbs of
Mokelumne Hill, is preparing for further devel-
opments. There is no question, the paper says,
but that Mr. Strange is in possession of a portion
of the old French Hill lead, one of the richest
deposits of auriferous gravel ever found in the
State. The only drawback to its working being
that he has an orchard of fine fruit trees grow-
ing on the ground. To get at the bonanza with-
out ruining his orchard is Mr. Strange's object,
and as he is an experienced miner he will un-
doubtedly accomplish it. There are not many
places in the world where mining and farming
are so closely connected pursuits as in this
instance.

The regents of Michigan University wish the
Legislature to make some provision for the
School of Mines, and ask for \$2,500 a year for
the purchase of books for the general library,
\$6,000 a year for support of the dental school,
and for several additional buildings. Edward
L. Walter, who has been assistant professor of
Latin in the University since 1863, has just
been awarded the degree of Doctor of Philoso-
phy by the Leipzig University.

THE VIRGINIA CITY papers draw a gloomy
picture of the destitution prevailing there.
Hundreds of men have been thrown out of em-
ployment, who throng the streets pleading for
work without being able to obtain it. Many of
these are men with families, who are thus de-
prived of support. This is attributed to the
depression in the mining share market, causing
slack work in the mines.

DISPATCHES from Sioux City, Iowa, state that
news has been received at Fort Randall
that twenty miners, returning from the Black
hills, have been killed by Crazy Horse's band,
at a place about 30 miles east of the hills.

The Nevada Transcript quotes rumor to the
effect that miners' wages in some of the mines
on the Ridge are to be reduced next month.

California State Geological Society.

The above-named society has been incorpo-
rated under the laws of this State for the pur-
pose of making a collection of mineral products
of the Pacific coast. The collection will be
donated to the State of California when it shall
become worthy of acceptance, upon the condi-
tion that proper care shall be taken of it, that
it shall be placed on exhibition free to all, and
that it shall not be removed from the city of
San Francisco. The second purpose of the so-
ciety is to encourage the study of geology in all
its branches.

Miners and prospectors have long needed
some place where, when visiting the city, they
could study the characteristics of the different
ores and minerals of the Pacific coast, and could
compare the varieties of ores. The society will
be able no doubt to give much valuable infor-
mation to those about to engage in new mining
and manufacturing enterprises by making known the
localities of useful ores and minerals.

The society has issued a circular appealing to
miners and those connected with mines to send
specimens of such minerals or metals as they
can obtain from any mine or deposit on this
coast, and also wall rocks, interesting minerals,
fossils, etc. It is desired that every mine on
the Pacific coast which has a name shall be re-
presented in the collection. A careful record
will be kept by the society of all specimens re-
ceived, showing the date, locality, donor's name,
and such other information as may be necessary.
The objects of the society are purely for the
benefit of the State and coast, and the manager
of Wells, Fargo & Co. has generously consented
to transport all packages addressed to the so-
ciety free of charge. It is requested, however,
that persons sending specimens send only such
as are characteristic and worthy of a place in
the collection.

The society is composed of the following gen-
tlemen: Melville Attwood, S. Heydenfeldt, Jr.,
Aug. J. Bowie, Jr., Thos. J. Owens, H. A. Cobb,
Jos. Roberts, Jr., Henry G. Hanks, Tod Robin-
son, and Ferdinand Vassault. The Directors
are: Henry G. Hanks, President; H. A. Cobb,
Vice-President, and S. Heydenfeldt, Jr., Secre-
tary. These gentlemen hope, by individual ex-
ertion and the assistance of others, to make a
collection worthy of the name; and as it will be
kept in this city, it will be available to all. It
is not intended to compete with or detract from
the large and growing collection at the State
University, but as that is at Berkeley, it is
practically inaccessible to the ordinary visitor
to this city, and a collection here will be much
more convenient. The bias of this society will
be in the direction of economic geology, and to en-
courage the development of all mineral products.
The gentlemen who have organized it will do
everything in their power to gather a fine, large
collection, and persons in a position to aid the
object need have no hesitation in forwarding
specimens, as they may feel assured that they
will be applied to the legitimate purpose for
which they are intended. The proper address is—
"California State Geological Society," San
Francisco, Cal.

Mining Stocks.

The mining stock market of this city has
been in rather a mixed-up condition of late, and
the newspapers are full of articles and commu-
nications concerning the various branches of
the subject. Stocks kept going down until the
bottom nearly dropped out, as the phrase is,
when suddenly prices started up with a jump,
catching a great many "shorts," and causing
financial embarrassment in various quarters.
The advance, curious to relate, seems to have
caused a great deal more disaster than the de-
cline. The long-continued decline and depres-
sion caused a depreciation in values which was
very alarming in the aggregate amount. At
one time the depreciation on several leading
stocks from highest prices in March to lowest
prices this month amounted to over one hun-
dred and twenty millions of dollars, or nearly
70 per cent. The depreciation in the two bo-
nanza mines was over sixty millions, or about
60 per cent.

There has been some pretty severe criticism
indulged in concerning the action of the cele-
brated mining firm of Flood & O'Brien, who
control the destinies of the bonanza mines.
It was stated that they could have sustained
the market during the late bad break, by stat-
ing publicly the exact condition of the mines
under their control, and denying the rumor
that Consolidated Virginia would pass the di-
vidend; or on the other hand, giving the reason
for not paying the dividend. We have pub-
lished the proceedings at the annual meeting of
the company, so that our readers are familiar
with the controversy which occurred there.
We are not aware that it has ever been the
custom for mining trustees or controllers of
mines to state to the public what they were
doing or about to do, except at the annual
meeting, and by the weekly or daily letters of
the superintendents on file at the offices of the
companies. As for assenting to or denying
street rumors authoritatively, it is seldom done.

That a time will come when the knowledge of
the doings of a mine will be as much the prop-
erty of one stockholder as another, we sincerely
hope, but it has not been a common custom
heretofore.

Without intending any special defence of the
firm mentioned, we are unable to understand
why, because the market is depressed, they
should shoulder the whole blame, any more
than they deserved the whole praise when
everything was up. They were praised without
 stint when they prophesied dividends for many
months ahead, but we cannot see why it is their
fault that dividends cease. We must say, with-
out prejudice, that as we understand the thing
these bonanza mines have been managed in a
first-class and at the same time economical
manner. We are not aware of any previously
worked mines giving even a proportionate
record. The history of mining management on
this coast is not so brilliant as to furnish many
examples of so large a proportion of gross earn-
ings paid to stockholders in dividends. Many
examples might be cited to show that when
large earnings were really made, the outside
stockholders got none of them. If the bonanzas
hold out dividends can be paid, but if ore gives
out, water comes in, ventilation is bad, and
hoisting facilities are not available, dividends
cannot be paid unless these difficulties are re-
moved.

It seems to have become quite the correct
thing to vilify the persons named if anything
goes wrong in any direction. It is a penalty
they pay for their positions as managers of the
leading mines. But the idea that any one or
two men can exercise supreme control over a
market such as this is absurd. They are re-
presented as having striven eagerly to depress
their own property, or that of which they own
more than any one else. The mines come into
prominence simply from their wonderful devel-
opments, and when the ore gives out the mine
must be worth less than it was. The stock
speculations of the bonanza firm they may keep
as private as they choose, but the mining devel-
opments are bound to come out and, as far as
we know, the work in the mines has been very
systematically and economically carried on.

The proof of this is shown in a statement by
a writer on the Commercial Herald, where it is
stated that 72% of the gross yield of the Con-
solidated Virginia and California mines has been
paid out to stockholders in dividends under the
present management, while the very best man-
aged among other mines on the Comstock, has
never paid more than 50% of the gross yields to
shareholders. In July California sold at \$56 per
share, and since then has paid dividends to the
amount of \$12 per share, while its selling price
on the 13th of January was \$45 per share.
Con. Virginia sold in July at \$45 per share, and
on the 13th of January at \$35 per share, having
in the meantime disbursed dividends of \$10 per
share. In other mines the depreciation was
still greater. For instance, Alpha in July was
\$47, and January 15th it was \$12. In the same
time Belcher fell from \$18 to \$8; Bullion from
\$42 to \$8; Exchequer from \$17 to \$4; Con. Im-
perial from \$6 to \$1.37; Justice from \$26 to
\$9.50; Kentuck from \$13 to \$4; Ophir from \$50
to \$16.50; Savage from \$22 to \$7.50; Sierra
Nevada from \$17 to \$5; Union from \$17 to \$7;
Mexican from \$40 to \$14; Yellow Jacket from
\$30 to \$9.50; Crown Point from \$12 to \$4.75,
and Chollar from \$100 to \$46.

Reports of all kinds are prevalent in the
present state of the market, and people who
gamble in stocks must take their chances.
When they lose, however, they should grin and
bear it, and not lay the blame on others. We do
not care to give any great amount of space to a
record of stock manipulations, but are always
glad to chronicle the facts connected with leg-
itimate mining operations.

Decision in the Debris Case.

Judge Sexton delivered his charge to the jury,
on Monday, in Sacramento, in the case of
Atkinson vs. The Amador mining company, to
recover damages for injury to his land by the
mining debris of the company, telling them that
they had nothing to do with the question of
titles raised by the defence, but were simply to
decide whether any damage had been done to
the land in question, and assess such damages.
After being out three hours the jury brought in
a verdict of \$4,000 for plaintiff. The judge
granted a stay of proceedings for 60 days.

THE PICKERING GOVERNOR.—Messrs. Neylan
& Young, agents of Cameron's pumps, machin-
ist's tools, wood working machinery, etc., are
also sole agents for the Pickering governor,
now being introduced on this coast. This gov-
ernor has received medals and awards at various
international and local exhibitions, some of which
are mentioned in the advertisement in another
column.

LAST season the Mackey & Fair flume brought
down from the summit of the Sierras 15,000,000
feet of timber and lumber, and 75,000 cords of
wood. All of this has reached the Comstock
via Huffaker's and per the Virginia and Truckee
railroad, and most of it has been consumed.
About 500 men have been employed this season
in preparations for next season's run.

been organized in Inyo county.

Comstock Papers.—No. 14.

The Name and but Little Besides

As we have seen, the various mines situated on the Comstock lode were named, for the most part, after the men who first took up claims thereon, or those who purchased from these original locators. Both of these parties, with a few exceptions, disposed of their interests at an early day, not a single one of the men whose names are attached to these mines having long remained a large owner in any of them. It is probable enough that these pioneers do not today own so much as a share in a Comstock mine, unless it be some of the very low priced ones. More than one-half of these men are, in fact, now dead, few of them while living having been distinguished for that foresight and thrift, without which scarcely any secure wealth.

The Men of Nerve and Courage Come In for a Share.

Before dismissing this branch of our subject it may, perhaps, be proper to mention still another class of adventurers, who, repairing early to these new-found silver mines, managed, without money or hard labor, to secure small and sometimes very considerable interests in some of the most valuable and actively productive claims on the great mother lode. These men belonged to that class, numerous in frontier countries and rough communities, who, preferring excitement and danger to the drudgery of hard work, are apt to be chosen to fill the offices of marshals, sheriffs, constables, etc., positions which more quiet and peace-loving citizens do not often covet, and for discharging the duties of which they are not always well fitted.

Now, so it was, many of these pioneer claim-holders were a good deal this stripe of persons themselves, or a kind whose experience lead them to readily sympathize with the bold and adventurous. Some of them, too, were a little uneasy as to the tenure whereby they held their possessions, being nothing loth to strengthen the same by an alliance with these practitioners under the shotgun and revolver code. Hence the transfer to these latter of divers and sundry feet in the rich claims at Gold Hill was a thing of frequent occurrence. As a general thing, these were not men of a noisy and turbulent manner or quarrelsome disposition, given to bluster and exhibitions of brute violence. On the contrary, they were more often noted for their quiet and even gentlemanly deportment, but of firm nerve and cool and desperate courage. Many of them had been engaged in deadly affrays, but these had mostly occurred in the discharge of their official duties, or, if of a personal kind, had not often been provoked by themselves.

Tom Peasley, John Blackburn and Tom Andrews

Might be cited as good examples of this school of men. Blackburn was killed at Carson City, December, 1861, by Bill Mayfield, a desperado and gambler. He was at the time marshal of the Territory, Mayfield having been led to commit the assassination through apprehension of being arrested by the officer. The killing was done in the early evening, in a well-lighted and crowded saloon, and was an act of wonderful daring on the part of the murderer, who approached his victim openly and while surrounded by his friends, and stabbed him to the heart, after which he marched out, flourishing his bloody knife in defiance and made good his escape through the aid of confederates outside. Blackburn, as he saw his adversary approach, drew his pistol, and would probably have killed him, had not his own friends, by injudiciously interfering, defeated his purpose. With his last gasp he leveled his weapon upon the retreating assassin, but fell dead before he could draw the trigger, his eyes burning with a fearful desire for vengeance. Blackburn, when entirely himself, was averse to acts of violence, though one of the bravest men that ever lived. When excited with liquor, however, as occasionally happened, he was a most dangerous man, attacking, without discrimination, his friends and his foes. Only a few days before his death, being slightly under the influence of liquor, he assailed and would have killed Wm. M. Stewart on the streets of Carson, but for the prompt interposition of Thomas Hannah, then with Stewart, a member of the Territorial legislature. The provocation given for this deadly assault was not only trivial, but almost wholly imaginary. Mayfield, after being for sometime concealed in Carson City, and nearly perishing with cold, his limbs having been badly frozen, was arrested, but afterwards succeeded in making good his escape

and fled to Montana, where he was killed in some gambling or other brawl a year or two later.

Peasley, while being the peer of Blackburn in point of courage, was at the same time a most genial, kind-hearted and companionable sort of person. He was also noted for his splendid physical powers, being at the same time a young man of intelligence, and by no means deficient in fine moral qualities. The incidents connected with his death were not very unlike those that attended the killing of Blackburn, the moving cause consisting in part of a personal grudge and in part of political differences. He, too, was killed in a saloon in Carson City, his assailant coming upon him unawares and shooting him fatally. With a pistol ball through his most vital part, such was the strength and will-power of the wounded man that he seized his murderer and, crashing him through a closed door, drew his pistol and deliberately shot him dead, falling the same instant, himself a corpse, upon the

Mechanics' Institute Concerts.

The trustees of the Mechanics' Institute have arranged to give a series of eight instrumental and vocal concerts, the object of which is to replenish the treasury of the Institute, which has become exhausted in consequence of the recent purchase of books and expensive alterations. The concerts will be given each Saturday evening, in a hall 200 by 100 feet especially fitted up in the Industrial Pavilion, and will be on a scale of unequalled excellence. The services of Mr. Rudolph Herold have been engaged as musical director and Mr. W. A. Andoe, many years manager of Gilmore's celebrated band, has been selected as the business manager.

A subscription list has been opened at the librarian's desk, and at the principal music stores of this city, the price of the season tickets having been fixed at four dollars, entitling

Mechanical Ore Concentration and Separation—No. 19.

(Written for the Press by FRANCIS M. F. CAZIN, M. E., Santa Fe, New Mexico.)

Six, or at least four, sizes should be determined on to be acted upon by the jigs, and all of one-half millimeter (a millimeter equals 1-25 of an inch), and smaller sizes should be kept out and treated as slimes, of which I shall speak specially. Experience has proven that proper series for classification are to be considered, viz., one, two, four, six and eight millimeters, or one, two, three, four, six and nine millimeters; or for finely disseminated ores, one, one and a half, two and three millimeters, or one, one and a half, two, three, four and five millimeters.

To illustrate a proper arrangement I select the series, one, two, four and six millimeters. To effect this arrangement the dry screen under the rollers should have perforations of six millimeters in diameter, so as to pass back by re-elevation what is not broken to this size at least. All that has passed the six millimeter perforations should drop into a single screen of three millimeter perforations in order to divide the entire bulk between two other screens, of which one is a single one with one and a half millimeter perforations, and the other a double screen, having inside one and a half millimeter perforations and outside, half a millimeter perforations.

This will result in the following: For cleaning table (a) slimes less than one-half millimeter; material for jigs (b), fine sand (one-half millimeter to one and a half millimeter); (c) coarse sand (one and a half millimeter to three millimeters); (d) fine grains (three millimeters to four and a half millimeters); (e) coarse grains (four and a half millimeters to six millimeters).

The single screens are best of the construction heretofore referred to—conical. For the double one the accompanying engravings show the proper style. The speed should not be in the middle of the screen, at circumference, more than from four to six feet per second. Figures A B and C show the double screen with stuffing-box attachment, the shaft being a wrought iron pipe, with holes so as to sprinkle water over the entire inside of the screen. The hopper delivers the ore on one side of the shaft, or over it on two sides, as indicated.

Screens made of wire cloth do very imperfect and unsatisfactory work. They should be perforated steel or copper, and of as heavy material as the perforation will permit. The screens with horizontal or inclined center shaft have been in general use for a long time. The author experimented largely with funnel-shaped screens, revolving on a vertical shaft fed in small streams all around their rim, and for jiggings sizes only they have more capacity than any others.

WEBSTER'S UNABRIDGED DICTIONARY.—It has now stood the test of time, and received in approval not only that popular verdict which in the United States has called for over 50,000,000 copies of the Webster series, but the thorough endorsement of our best scholars, as put forth individually, and in the pages of the authoritative periodicals. It is not only, to quote Professor Stowe, "in many respects the greatest literary work which America has ever produced," but it is in many respects the greatest literary work produced by any nation or age.—*New York Mail*.

LUMBER.—The Seattle Tribune says: The Port Gamble saw mill cut in 1875 40,000,000 feet of lumber, 16,000,000 laths, loaded 88 ships, and bought (by the Puget Mill Company) 54,000,000 feet of saw logs. At Port Blakely, 30,000,000 feet of lumber, and 10,000,000 laths were cut and 70 cargoes sent abroad. The report from Port Ludlow is of 20,000,000 feet cut. Schooners and barkentines of an aggregate tonnage of 1,600 were built at that place from lumber cut in the mill.

The Northern Belle company paid its twentieth dividend on the 15th inst. During the two years the mine has been worked it has netted \$1,300,000; at least it is so reported. It is now claimed that the February dividend will be increased to \$1.50, leaving a surplus on hand.

The shipments of Seattle coal during the first thirteen days of January ran up to 5,700 tons, or, not including one Sunday not worked, at the rate of 475 tons a day.

REVOLVING WET DOUBLE SCREEN.

floor. Both Peasley and Blackburn had been quite largely interested in different properties on the Comstock lode, and were at the time of their deaths owners in some of the more valuable mines along it. Andrews, of whose name we have made mention, was also at one period interested in some of the Gold Hill grounds. After many rough and varied experiences these interests have slipped away, but the owner still survives, with seemingly a good many years of active service still in store for him.

We might adduce many other examples of men belonging to this class, but need not multiply them here, the cases already cited sufficiently illustrating the anomalous condition of affairs that made it possible for such valuable interests to be secured by considerations and services of the kind alluded to.

COAL IN LOS ANGELES.—A dispatch from Los Angeles says: Parties are engaged in prospecting for coal in the Arroyo Seco, immediately adjoining the city on the east. Some fine specimens have been discovered, and the prospectors expect to strike a vein in a few days. Coal has now been found near Lyon's station, in the Cañuena range, near Santa Monica, at several points in the San Fernando mountains, and in different sections of the southern portion of this county, with surface indications at various points in the neighborhood of this city. The matter is attracting the attention of capitalists, and prospectors are urgently invited to bring specimens to the city in order that they may be tested. If the test is satisfactory, a large amount of capital will immediately be invested in developing the claims already located, and prospecting for others will become lively.

ANTIMONY is selling in Liverpool at £55@57 per ton for French star regulus.

the holder to one reserved seat during the entire season. Lovers of music will have here a fine opportunity to indulge their taste, and at the same time aid a worthy object. The seating capacity of the hall will be for 3,500 persons. The most complete arrangements have been made to make the concerts a success, and the best available home and foreign talent has been engaged. The object is a deserving one and we hope that all who can will purchase one or more season tickets, even if they cannot attend all the series.

BULLION SHIPMENTS.—Since our last report shipments from the prominent mines have been as follows: Modoc, January 17th, \$5,630; California 18th, 19 bars bullion, valued at \$75,108.82—total to date, \$209,004.73; Con. Virginia, 18th, 13 bars bullion, valued at \$45,442.94—total to date, \$209,395.93; Comanche, 16th, \$6,106; Northern Belle, 16th, \$10,361.21; California, 20th, \$80,181.99—total to date, \$289,186.72; Modoc, 19th, \$5,080—total to date, \$82,277; Con. Virginia, 20th, \$16,118.88—total to date, \$225,514.81; Modoc, 21st, 230 bars, valued at \$5,390—total to date for January, \$87,667; Tybo Con., 17th, \$5,810.62—total to date, \$31,390.50; Arizona, 21st, \$1,853; Chollar, 22d, \$6,860.88; Con. Virginia, 23d, \$49,622.73—January account to date, \$275,137.54; California, 23d, \$198,673.43—January account to date, \$487,865.15; Northern Belle, 18th, 7 bars, valued at \$12,019.95; Manhattan, 24th, \$12,500.

SINCE the cessation of the rain the work of erecting the Southern Pacific work shops is being vigorously pushed at Los Angeles. Over 300 men are now employed on the grounds. The framework of the machine shops was placed in position Tuesday.

Base Bullion.

Smelting Works in Utah.

The Salt Lake Tribune in an article on the above subject gives the following list of smelters in Utah.

The Flagstaff Smelter.

Situated at Sandy station, on the line of the Utah Southern railroad, is conducted in first class style. Everything about the premises goes forward with the regularity of clock work. Each man knows his duty and performs it. The discipline is regular, and strict compliance is exacted from all. A man who gets intoxicated is at once dismissed, and is never again employed, and like Squeers, the management compels everybody engaged about the smelters to take a dose of medicine before breakfast as a preventive against leading. Ninety men are employed about the works, and 120 tons of ore is reduced every 24 hours, yielding about three car loads of base bullion daily, a greater quantity than is produced at any other smelter in the Territory. The property is owned by the Flagstaff mining company, and for the space of about a year prior to the middle of last September, was lying idle, when Messrs. Mathier & Geist, of Salt Lake City, leased it and fired up one furnace. This enterprising firm, with Mr. Mathier doing the business in the city, and Mr. Geist, who is an educated as well as a practical smelter, managing the works, at once commenced making the needed repairs, preparatory to running all four of the stacks. In less than three months improvements at a cost of nearly \$40,000 had been made, and all four of the furnaces fired up. One of the largest and most valuable improvements put in by the lessors, is an 80-horse power engine, while the old one, which is in excellent repair, will be kept in condition in case of accident to the other. The whole blast of the smelter is now 120-horse power. Fume condensers have been put in, so that the smoke from each furnace is forced through a series of chambers, where the dust, which assays about 35 per cent. lead and 24 ounces in silver, is saved, and after being properly prepared, is put through the furnaces with matte. A reverberatory furnace for roasting matte and refractory ores, has just been completed and fired up. A considerable quantity of broad and narrow gauge railroad switches have been put down about the works, and extensive ore platforms constructed. Two large reservoirs at a considerable cost have been built east of the smelter, so that a supply of water in any weather may not be wanting. Other improvements are being made, and when the company gets a new system of roasting refractory ores successfully, the Flagstaff will be one of the institutions of the country.

This smelter is running all the ore produced from the Flagstaff mine and portions of that from the leading mines of Little Cottonwood and Bingham. From these ores the short time the smelter has been in operation 200 car loads of base bullion, worth \$2,000 per car, have been produced. At the present time there are about 5,000 tons of ore on the platform ready for smelting, while an immense supply of coke and charcoal is in sheds for a long winter's run.

The Germania Smelter

Is situated on Little Cottonwood creek, about six miles south of Salt Lake City, and on the line of the Utah Southern railroad. It is owned by a foreign corporation, and perhaps is one of the most complete works of the kind on the Pacific coast. It is conducted with skill and energy, and turns out the purest lead bullion produced in Utah.

The machinery about this establishment is of the best manufacture, and does its work constantly and without stoppages. The engine, which has been in use four years, is a very fine one, of 40-horse power, being of ample capacity to keep up the blasts of both the furnaces, while the pump, by the timely use of which the works have been saved several times from destruction by fire, is one of the neatest to be found at any of the smelters. It is capable of throwing 300 gallons of water per minute. During the past year new improvements have been made. A new steam boiler to supply the place of the old one has been put in; new refining works for separating the silver from the base bullion have been constructed and will be in operation in the course of a few months, and other improvements of a minor character have replaced less convenient and substantial things about the place. At present the Germania has both of its water jacket furnaces in full blast. They are in point of safety to the health and lives of those employed about them, unsurpassed by any furnaces at the smelters of Salt Lake county. The fume condensers are almost perfect, so that the poisonous dust arising with the smoke is caught before it reaches the open air, while the feed doors of the furnaces are so arranged as to make it impossible for the fumes to escape into the building and lead the men. The ores smelted at these works are brought from various parts of the country. Besides those produced from Utah mines, which form the basis of the supply, a considerable quantity of high grade ores from Montana and Idaho is used in connection with the low grade lead ores from our own mines, for the purpose of raising the percentage of silver in the bullion turned out above the standard of 110 ounces to the ton, which gives the bullion a readier sale in the market.

The process of preserving the

Standard of Bullion

Is done in a manner peculiar to the Germania.

When the contents of the several classes of ores have been ascertained by sampling, a given quantity from each lot is spread out on the floor in layers one upon the other, until a pile of fifty or a hundred tons of all the requisite classes is accumulated, and then from this the furnaces are supplied, one pile being used up while another is being built. In this manner the grade of bullion produced is always kept approximately near to the required standard, so that the managers have an idea from day to day what will be produced for a week ahead.

On an average, 40 men are constantly employed, running two shifts every 24 hours. But the works are so perfect about the Germania, that leading is very rare.

During the past year this smelter has produced 1,700 tons of base bullion of the average value of \$235 per ton, or a total valuation of \$262,500.

The Sheridan Hill Smelter

Is situated at West Jordan on the Bingham Canyon railroad, and is built on one of the most eligible sites to be found in the country, with an ample and inexhaustible water-power privilege. It is understood to be the property of three Salt Lake gentlemen, it having fallen into their hands on a mortgage from the original owners. It is a good piece of property, and with some needed repairs and improvements in the style of the furnaces, it would rank among the best smelters of the country. Yet it has done, with its three stacks running only a portion of the time, a good year's work, giving employment to an average of 20 men the entire 12 months, and it has turned out 173 car loads of base bullion of 11 tons to the car, worth, according to Superintendent Rumfield's calculation, \$2,000 to the car load, or a total value of \$346,000. One smelter has been run on custom ores from the mines of Bingham and Cottonwood.

The Galena Smelter

Is situated at the same place as the Sheridan Hill and almost joins it on the north. This smelter, which is now in the hands of Captain Selfridge, has seven furnaces; three of them have been leased to Mr. L. E. Holden, who has torn out the old stacks and is replacing them with others of an improved pattern. They will be ready to fire up early in the spring. Of the four remaining stacks, two and some of the time only one is kept running, but they are large and of sufficient capacity to reduce all the ores the company may desire to handle during the coming season. In the last year 235 car loads of base bullion, or 2,470 tons, of an average value of \$1,600 to the car load, have been produced from the yield of the Jordan mine and custom ores from the Cottonwoods and Bingham. The Jordan company have in connection with the smelter a sampling mill, where they have sampled every fifth sack of the 12,350 tons of ore run through their smelter in the past year, as well as having much work of the same character for other parties. At present they sample about 300 tons each month, including that which they purchase for their own use. The business is under the able supervision of Captain Selfridge, who is running the concern to win, while Mr. G. P. Lockwood is in charge of the smelter and the gang of workmen, some 30 in number.

The Saturn Smelter

Is situated at Sandy station, and is one of the oldest smelters in the country. It is running only one stack, but since it has been under the control and management of Mr. John W. Kerr and other Salt Lake parties, it has been well conducted. One hundred and sixty car loads of \$2,000 to the car, is its product of base bullion for the last year. The old dump of slag is being overhauled for the malt in it, and will be put through the furnace with ore. At present the works are shut down for repairs and improvements, but they will be started up again in the course of a few days. This smelter is under the immediate supervision of Mr. A. A. Ganschatz.

The Mingo Smelter.

Or the Mountain Chief, which adjoins the Saturn, and has been lying idle for several years, has been leased by a Pittsburg company and put in repair. Two large furnaces have been built from the ground up, new machinery put in and other extensive and substantial improvements made. It is now one of the neatest and most convenient smelters in the country, of a capacity of 15 tons of bullion daily, and is under the management of men who have had life-long experience in the business.

The Wasatch Smelter

Is situated on the north bank of the Little Cottonwood stream opposite the Germania. It is the property of R. P. Lounsberry, and has been idle for a number of months. Recently, however, Conklin, Jones & Co., have leased it, put in a new water jacket furnace, erected a roasting oven, and made such improvements generally as will enable the lessees to do good and rapid work. They have a contract to run on a portion of the ore from the Old Telegraph mine in Bingham, and although it is found by other smelters that this ore is refractory, it is proposed to work it at the Wasatch by a process which will enable them to smelt it separately. The furnace has only been running one month, during which time about 100 tons of bullion have been produced. Seventeen men are employed at this smelter.

The American Smelter,

Situated at the same place, though about a mile off the line of the railroad, has been shut down for many months. It is understood, however, that an effort will be made to fire up its stacks

in the spring, by Mr. Oliver Durant, who holds a controlling interest in it.

The Morgan Smelter.

Situated on the south bank of the Big Cottonwood stream, and close to the line of the Utah Southern railroad, is a new work, and considering it has but one furnace, it is a very superior smelter, if the quality and not quantity of bullion produced by it are facts to judge from. It has been completed and running about 30 days altogether, during which time some 35 car lots of bullion have been turned out, the average capacity of the one stack being 16 tons every 24 hours. But owing to the limited supply of ore to be had at present, 12 tons is its average daily product. When it was first fired up, to test its capacity, it was put under full blast and given all the ore it could take. The result was, two car loads every 24 hours were produced.

A breakage in the machinery delayed operations for a week early in December, and the fact that a sufficient supply of ore is hard to get, cut the number of tons they could have produced in one month down to 350. Of course the furnace in this smelter is the chief feature, being the largest stack in the country. It is a water-jacket furnace, on which Mr. Morgan has a patent. Each of the four sides is hung to the deck beam by hinges, and the whole are kept in position by an iron belt, which may at any time be removed, thus permitting the jackets to be swung up to the roof of the building to allow of the repairs to the furnace, causing only a few hours' delay. Another improvement is found in the style of the tuyeres, the nozzles of which are so arranged as to keep themselves from burning out or clogging up with slag.

The blast power of this furnace is received from a turbine water wheel, run by a canal, four miles long, from the Big Cottonwood creek, and discharging at the mouth of the flume 1,000 cubic feet of water per minute. The machinery is all first-class, the buildings and coal sheds conveniently and substantially built, and when all the designed improvements are finished this will be a paying smelter, turning out a superior quality of lead bullion. Twenty-five picked men, all of extensive experience in smelting, and none other, are employed. They work eight hour shifts, and the company pays the highest wages. The smelter is the property of B. W. Morgan & Co.

The Davenport Smelter.

At the mouth of Little Cottonwood canyon, is at present shut down. It was run by Mather & Geist, the first nine months of the year, on Flagstaff and other Cottonwood ores, and during this time 200 car loads of bullion was produced, worth about \$400,000, but when the firm leased the Flagstaff smelter, they closed down the Davenport.

The Pascoe Smelter,

Situated above the Warm Spring bath house, within the limits of Salt Lake City, has run during the entire year with success, producing 190 car loads of base bullion of \$2,000 to the car. One water-jacket furnace only has been run, but another large one of a new pattern, the invention of Mr. Pascoe himself, is being put in, and will be fired up within a few days. A new roasting furnace is being built, and also a smoke stack and fume condenser. In connection with the smelter, a newly patented ore concentrator is in course of construction. It is an invention of Mr. Pascoe's own, and possesses some points of improvement. The jigger in a tub, crushing roller, rotary screen, and tossing tubs combined to constitute a continuous series of manipulations, by which the ore and waste material are separated, and all the mineral saved. And in these points the superiority and improvements consist. There is no doubt about the successful operation of the machine, as it has been tested and found to work to a charm. It will be put in operation in February, with some other improvements attached, which have not yet been patented. Mr. Pascoe is a gentleman who shows commendable enterprise in inventions looking to the successful reduction of our low grade ores, and in the concentrator, as well perhaps as in the style of his blast in the furnace, success has crowned his efforts.

The Chicago Smelter,

Owned by an English company, is situated at Rush lake in Tooele county, and is one of the most successful concerns of the kind in the Territory. It is complete in point of machinery and all the modern improvements, is ably managed by Mr. William S. Godbe, and has been conducted during the past year with enterprise. Out of custom ores and those from the Queen of the Hills, 240 car loads of base bullion of the average value of \$2,000 per car have been produced. The report of the 11 months ending November 30th, 1876, shows the product to be 4,778,691 lbs. of lead, 232,672 ounces of silver, 5803 ounces of gold. The estimate for the 12th month would raise the product to 2,217 tons of lead, 254,815 ounces of silver, and 643 ounces of gold.

The Watterman Smelter

Is situated on the head of Rush lake at Stockton, in Tooele county, and is owned by Isaac S. Watterman, of Philadelphia. It is a smelter of two stacks, both of which have been running during the greater part of the past year with perfect success, on the product of the Hidden Treasure mine, and custom ores from Dry canyon and Ophir. Since the 1st of January, 1876, 2,100 tons of base bullion has been turned out at the average value of \$200 per ton, or of a total value of \$420,000.

The Longmaid Smelter

At Rush lake, turned out a large quantity of

bullion while it was running, but unfortunately it has suspended operations. It was leased by Mr. Longmaid, together with a number of mines in Ophir and Dry canyon, in the fall of 1875, and was kept in active operation from the time it fired up until it was closed down, and was purchased by the Chicago mining and smelting company. The parties who were conducting the enterprise are now going through the bankrupt court, and of course have a delicacy about disclosing the state of their business, but well informed gentlemen estimate the product of the smelter for 1876 at 1,700 tons of bullion, of \$340,000 value.

The Bullion Smelter

Is situated in Dugway district, 60 miles southwest of Stockton in Tooele county. It is the property of Adams, Smith & Son, of Chicago, who own a number of valuable mines in Dugway district, and are operating there as an incorporation, styled the Bullion mining and smelting company of Chicago. The smelter consists of but one stack at present, and has been in operation only a week, but it is the intention of the company to build an additional furnace as soon as needed.

The Mariposa Estate.

The following account of the operations of the Mariposa land and mining company is from a recent issue of the *Stockton Independent*, the editor of that journal having visited the ground lately:

Probably no tract of land in California has afforded subject for more comment than the tract known as the Fremont grant, in Mariposa county. This tract was located under a Mexican grant and is the only one of those unpopular land titles located in the mineral belt of California. During the earlier mining era, when the gold seekers were exploring every river, gulch and ravine in their search for the precious metal, the fact that the Fremont grant was all claimed as private property was the cause of much complaint, and Fremont was severely censured by a class who then were unalterably opposed to the sale of mineral land by the government, for appropriating too large a tract, and the government and its courts shared with Fremont the curses of the miners, who were restricted from freely mining on this estate. Fremont, however, was unable to make his acquisition of any particular value, and although he attempted to open and work some of the rich quartz lodes then known to exist thereon, his efforts were not peculiarly successful. Trenor W. Park finally obtained control of the property and with his usual energy and enterprise proceeded to develop the mines. Although his policy was to make the most of this possession in the least possible time, his administration of the affairs of that estate was generally more satisfactory than any before or since. He constructed mills, built roads, and opened up and worked mines, employed many hundred men at good wages and gave to Mariposa county, or especially that portion of it covered by the grant, the liveliest times it has ever seen. During his administration Bear Valley, Mount Bullion, Princeton and Mariposa were populous and prosperous mining camps, and the result of his enterprise was undoubtedly very satisfactory to himself, as he must have extracted vast amounts of gold. When he retired from the management the mining interests seemed to decline. The property passed into the hands of a joint stock company, being principally owned in the Eastern States, but on account of injudicious and extravagant management it has been a very unprofitable investment. Scientific superintendents, with large salaries, have been placed in charge of the property and expensive mills and machinery erected and placed in operation, but the ore worked has not paid for the outlay. Dodge Brothers, of San Francisco, having demands against the company, secured control of the estate for a short time in order to collect their debt, and it is generally believed that they succeeded in making the property productive, but of course such management was of no particular benefit to the Eastern stockholders. During all the years from Park's administration down to the present, the property has been regularly deteriorating in value. The improvements in the shape of mills, etc., have been going to decay, several camps that were once populous have become deserted, comparatively few men have been employed and oftentimes the finances of the company have run at a very low ebb. Little work has been done excepting what has been done on the Pine tree and Josephine lodes, situated near the town of Bear Valley, on the northwest side of Mount Bullion. Immense amounts of gold have been taken from these two veins, the rock having been transported down the mountain to the mills on a railroad constructed during Park's administration. Work was commenced on these veins at a point nearly 2,000 feet above the river and a grade was built by Park thence to the river, a distance of four and one-half miles, and the cars loaded with the ore ran down by their own gravity, a brakeman conducting the train and regulating its velocity. The cars were hauled from the mill back to the mine by mules. With this way of working, the rock paid very handsomely, even after a depth was reached below the upper end of the railroad and it had to be raised for a considerable distance by steam power.

A Change in the Management of the Affairs of the Company

And a thorough examination of the situation caused them to come to the conclusion that

raising for a considerable distance merely to drop it a greater distance to the mill was not good policy, and consequently it was decided to commence a tunnel at high-water mark on the Merced river and run it into the mountain until the lodes were reached, and thus work the ore beds from the level of the mill and save the expense of hoisting. As there are numerous leads of quartz running through the mountain it was reasonable to suppose that other valuable deposits might be struck before the objective points, the Pine Tree and Josephine lodes, were reached. The tunnel was commenced and work thereon has been energetically prosecuted with all the improved appliances now in use, and it now extends into the mountain 2,300 feet from its mouth on the river bank. Much exceedingly hard rock has been encountered, yet the boring goes on at the rate of 50 feet per week. The drilling is done with what is known as the

Burleigh Drill, Worked by Compressed Air.

This is comparatively a new invention and in our estimation one of the most important made within the last score of years. At this mine the compressor is located at the mill on Merced river and worked by water power, the air is compressed into a receiver from which a two-inch wrought iron pipe runs into the tunnel. Standing upon wheels resting upon a railroad track, is an iron frame-work supporting the machinery for operating the drill. This frame-work can be moved backward and forward upon the track, the connection between the iron pipe conducting the compressed air to the machinery being made with heavy gutta percha hose. The machinery for driving the drill is constructed upon a similar principle to that of a steam engine, the compressed air taking the place of steam. It is so arranged that a hole can be drilled anywhere in the tunnel at any angle. The drill moves backward and forward, like a piston to a steam engine, and strikes the rock with great force at a velocity of 300 blows per minute, penetrating the hardest rock at the rate of one foot per minute. To prevent the drill from heating by this excessive friction, small water pipes are arranged which force a stream of water into the drill hole and it also removes the rock chippings made by the drill. At present two drills are used and a number of holes are bored in the face of the tunnel at the same time. Then the frame-work supporting the drills is moved back in the tunnel, the holes are charged with giant powder and all exploded at once by means of a galvanic battery. By this means the whole expansive force of the powder is utilized, and the result of the explosion is much more satisfactory than it would be if the charges were separately exploded. There can be no question as to the ultimate result of the systematic and thorough prospecting of

This Rich Mineral District.

Which is now being made by the managers of the Mariposa estate. The tunnel has already cut veins of quartz that would pay for working, and last week a six-foot vein was struck that is rich in gold, and pronounced to be similar in character to the ore formerly taken out of the Pine Tree vein, if it is not actually that vein. Arrangements are now being made to commence working the ore from the veins already opened, while work upon the main tunnel will be continued. A new compressor, the largest ever constructed, is now being erected, which, when completed, will afford sufficient power to run at least six drills. The iron pipe leading the air into the tunnel from this compressor will be six inches in diameter. Complete arrangements have been made for exhausting the tunnel of foul air and the powder smoke which otherwise would greatly retard, if not entirely prevent, the prosecution of the work. A large galvanized pipe has been extended to within a short distance of the farther end of the tunnel, and at the lower end of this pipe is a fan mill, run by water at a great velocity, which draws the foul air from the tunnel and thus causes a current of pure air to circulate through it from its mouth. In fact all the arrangements for prosecuting this great work are complete and the latent wealth of Mount Bullion will soon be developed. The company are now erecting a new mill and as soon as the machinery of the new compressor is in position, numerous stamps worked by the extensive water power furnished by the Merced river will be pounding the hard rock to powder in order that the precious metal it contains may be extracted and made to add to the wealth of the enterprising men who have manifested so much energy in prosecuting this great work. Unless the present outlook is very deceptive, before the next three years the Mariposa estate will be one of the best mining districts in California, and the impecunious miners who will then be able to obtain work at fair wages and the stockholders who will begin to draw dividends from their investment will undoubtedly agree that it is better for the interests of the State to have the mineral land of the United States sold so that capital can be obtained to develop its mineral wealth.

Successful Working

We are pleased to be enabled to chronicle the entire success which has attended the operations, since it commenced running, of the mill at Pinto, which has been leased by the Geddes & Bertrand company. It was feared that ore from the company's mine at Secret canyon could not be successfully worked by the mill process, at least without a long and expensive series of experiments, but the operations of last week have demonstrated beyond cavil that such fears were

groundless. The mill has 20 stamps, but thus far only 10 have been running, and during the time 11 tons per day have been worked, yielding upon an average \$90 per ton without roasting. It worked fully up to 78° of the pulp assay and Mr. Mee, the superintendent, is confident that when some necessary changes have been made in the pans, it will work to a considerably higher figure. The other 10 stamps will be started to-day, raising the crushing capacity to from 20 to 25 tons per day. There are at present about 500 tons of ore at the mill, about the same amount on the dump at the mine; at least a thousand broken in the breasts, with all the indications favorable for an immense quantity easily accessible beyond. Now that the reduction problem has been successfully solved, the profitable working of the mine is placed beyond all question and we shall look with confidence, in a short time, for a series of bullion shipments which will produce a rapid elevation of the stock in the boards at San Francisco. The road from the mine to the mill is never obstructed with snow except for a short time during the hardest winters, and with an ordinarily favorable season ore transportation can be continued until spring. We know of no property in Eastern or Middle Nevada which promises so favorable results for the next few months as the Geddes & Bertrand. —Eureka Sentinel.

El Paso District.

The San Benito Advance gives some facts about this old district, in Slate range, San Bernardino county.

The El Paso district is situated in the Desert range, on the southern end of the chain of mountains in which the rich mines of Coso, Darwin, Lookout, Panamint and other well-known camps are located.

The district was discovered in 1860, but the attractions of Washoe and the famous lodes of the Comstock drew the crowd of prospectors and adventurers in that direction; consequently most of the claims were abandoned. Malcom and his party have relocated some of these ledges and discovered several more, all of which, so far as they have been worked, look splendidly, and judging from the samples of ores which we were permitted to inspect, the mines are very rich. We have had some experience in quartz mining countries and do not remember of ever seeing finer or richer silver-bearing ore. The ledges vary from four feet to twelve feet in width and are traceable on the surface for miles. Should they hold out as well as they promise, there is no doubt that El Paso will soon become one of the most important mining camps in the State. A shaft 80 feet deep has been sunk on one of the largest leads—on which a tunnel is also being run—and at that depth the ledge continues to grow wider and better, thus giving evidence of the permanency of the mines. The ore is easily extracted and assays from \$50 to \$10,000 per ton. Lumber sells for \$100 per thousand and the scarcity of timber in the immediate vicinity causes some inconvenience.

There is no mill in the district yet, but a company from Los Angeles intend building one in the spring, and as there is a considerable quantity of ore already on the dumps, it will be apt to be kept pounding pretty lively for a time and no doubt will be followed by others. The altitude of the mines is 6,000 feet above the ocean, and the locality is a true desert in all the prominent features. But one lonely willow tree graces the arid waste; greasewood, sage brush and cactus are found everywhere, and they grow large enough to make excellent fuel. Numerous springs throughout the mountain districts supply an abundance of good water.

Within 25 miles of the camp there are (gold) placer diggings which prospect from two cents to a bit to the pan, but cannot be worked with profit owing to the scarcity of water. The famous Borax lake, owned and worked by the Searls Bros., is also in this vicinity. These works employ from 30 to 40 persons, and ship to San Francisco monthly 100 tons of borax, which is said to be of the purest and best quality.

Smelting.

What is Daily Lost.

Have we reached the limit of our inventive faculties in our smelting processes? We have made an immense stride from the first crude operations of our early history, and the present furnaces are a vast improvement, but if one examines the methods he will find that we are very far from perfection, the loss entailed by the present workings being fully 20% of the assay value of the ores extracted. The largest item of loss to the smelter is the volatilization of the ore, resulting in a dust carried off with the fumes, aided by the force of the blast. It is estimated that this will amount to 13% of all the ore smelted. The loss in the slag and iron will reach from seven to eight per cent. more, and it is doubtful if the vein matter is worked even as close as that. The total loss will aggregate at least 20%—a fearful waste and serious in its results. There have been many attempts to solve the dust problem, and it is claimed that at some of the furnaces where it is reworked that the lead and silver are extracted by this final process, but upon examination it will be found that the operation reduces the capacity of the furnaces to such a degree that

there remain no practical results. The Eureka Consolidated recognizes this fact and contents itself with saving the dust from the chambers, and storing it in anticipation of some cheap method of reworking. On the contrary, the Richmond company mixes the dust with clay and feeds it to the furnaces in the shape of a slime, using about ten tons per day. Experienced smelters argue that nothing is gained by this method, even if the lead and silver are extracted by the second working.

The dust has already cost as much in the way of fuel and labor as if smelted by the first process, and its reworking represents 13% additional fuel, power and labor expended in expelling the moisture, and the capacity of the furnaces is reduced 10 tons per day, without any economical gain. The working capacity of the Eureka Consolidated furnaces are at least 10 tons per day in excess of the Richmond, and the company are accumulating a valuable property in the dust saved from their dust chambers. The desideratum is not a process that will extract the precious metal from the waste, but a more perfect smelting method, one that will prevent the original loss, or in other words, a closer working to the dry assay value. Our ores can be worked by no other known process, and nature has done a great deal to further our success in this line. The materials for fluxing are a part of the ores, or abound in the vicinity. We are highly favored in this respect, as there is no deposit of ore in the world that combines in so great a degree the elements necessary for their successful reduction. We have made progress in every direction but the improvement of our furnaces and reduction of the loss in waste; but here we are at a standstill. Every dollar gained in smelting the ore is a net increase in the value of our mines, a step forward in industrial progress, and will add to the further development of the resources of eastern Nevada. An experiment on a small scale was made by one of our mining superintendents, and was a success, but the furnace used in the test was so small that while demonstrating the practicability of the invention it gave no permanent results. We hope the gentleman will be induced to build a furnace of a capacity sufficient to test the merits of his invention, and that we may be able to record its complete success. —Eureka Sentinel.

SANBORN & BYRNES,

Mechanics' Mills, Mission Street,

Bot. First and Fremont, San Francisco. Orders from the country promptly attended to. All kinds of Stair Material furnished to order. Wood and Ivory Turners. Billiard Balls and Ten Pins, Fancy Newels and Balusters.

N. W. SPAULDING'S

PATENT DETACHABLE TOOTH SAWS.

Manufactory, 17 & 19 Fremont St., S. F.

Diamond Drill Co.

The undersigned, owners of LESCHOT'S PATENT for DIAMOND POINTED DRILLS, now brought to the highest state of perfection, are prepared to fill orders for the IMPROVED PROSPECTING AND TUNNELING DRILLS, with or without power, at short notice, and at reduced prices. Abundant testimony furnished of the great economy and successful working of numerous machines in operation in the quartz and gravel mines on this coast. Circulars forwarded, and full information given upon application.

A. J. SEVERANCE & CO.

Office, No. 426 California street, Room 1.

D. LANGELL'S ASTHMA & CATARRH REMEDY.

Having struggled twenty years between life and death with ASTHMA, I experimented by compounding roots and herbs and inhaling the medicine. I fortunately discovered a sure cure for ASTHMA and CATARRH. Warranted to relieve any case of Asthma instantly, so the patient can lie down to sleep. By mail, \$1.00 per box. Address D. LANGELL, Apple Creek, Ohio. For sale by Druggists.

\$55 or \$77 a Week to Agents. Samples FREE. P. O. VICKERY, Augusta, Maine.

MINERS, write for your paper.

Continued from page 53.

Casco and the Last Chance, all of which cannot fail to prove splendid property to their owners. The outlook is very favorable for that camp, and it ought to give employment to several hundred men the coming summer. Many of the failures which have attended mining operations in Owyhee for the past season can be attributed to the fact that the business properly. This has resulted in serious loss to many, and miners especially are sufferers. Operations are progressing swimmingly at the Belle Peck. There is a full force of men at work night and day. The main shaft is being sunk and stoping is going on over the tunnel. In every section of the mine the rock is looking first-rate. The Potosi is looking well. There is now a large quantity of rock at the mine awaiting crushing. It will be hauled to some of the mills in the vicinity shortly. Late reports from South mountain disclose the existence of quite a hopeful feeling among the residents of that camp. The mines are being worked by a limited force, and in the spring it is expected that operations will be carried on on a larger scale. Mr. Bowyer, the newly appointed superintendent of the company's operations there, was in town a few days ago. He is in a very hopeful mood concerning the future prospects of that camp. Douglas and others are working a claim about 300 yards west of the Belle Peck. They have a quantity of rock ready for crushing which is said to be unusually rich. There is abundance of gold in it. Rumors continue to prevail of the existence of a rich ore body in the 13th level of the Golden Chariot.

Utah.

NEW MILL.—Salt Lake Tribune, Jan. 18: The new five-story mill, recently erected by the Crimmon Mammoth company, in Tintic, is completed, and will be started up on Monday morning next, running on gold ore. Mr. M. Edwards, one of the lucky owners and proprietors, will go down to see the little beauty make her first run.

LEADS DISTRICT.—The rush to this district has "let up" to some extent, as far as broken men are concerned, and the present influx here is a more permanent lot of men, who come with means sufficient to remain and prospect for mines or work them by contract. This kind of men do not meet with disappointment as those who come here without means, and expect to find work at once or strike horn-silver on the surface. Capitalists are daily arriving, and we hear of a number who will no doubt invest and open out prospects and mines. Silver Reef City is building up rapidly, and contains at present 40 buildings and a number of miners' cabins. About eight buildings are in course of erection. Bonanza City is also improving, and now can boast of 15 buildings, consisting of one store, one saloon, one blacksmith shop, cabins, Barbree's office and a large carol. Several buildings are about to be built. The two towns are close together, and will make a large town after a while.

THE MINES.—The Leeds mining company have struck a good body of ore in their new shaft, at a depth of 85 feet. The ore is of a high grade. The mill is expected to start up about the 20th of next month. The boiler is in place and the battery is now up. When it starts up, everything will be lively here, and large shipments of bullion made. The Barbree & Walker are about completing the first winch in Leeds. They expect to start up in a few days and raise about 20 tons of high-grade ore daily. This mine is on the White road, and is a number of miles from the mine taking out good ore, ready for shipment or reduction here. Among them is the Bonanza, which is shipping to Pioche.

PATENTS AND INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

FOR WEEK ENDING JANUARY 16TH, 1877.

SOPA BEDSTADS.—Henry Comper, San Francisco. **CHECKS FOR METAL TURNING LATHES.**—Jay H. Harris, Sacramento, Cal.

TUBULAR GANG SAWS.—James A. Balch, East Portland, Oregon.

BELT SHIPPING ATTACHMENT FOR PULLEYS.—Rufus Denmark, Washington Corners, Cal.

MECHANISM FOR LESSENING DRAFT OF VESSELS.—Edward Ellison, San Francisco.

GANG PLOWS.—William Fruhling, San Jose, Cal.

PORTABLE FIRE PLACES.—Theodore C. Nativel, San Francisco.

REFRIGERATORS.—John W. Stewart, San Francisco.

RAILWAY CARS.—In Samuel R. Wallace and Oliver V. Wallace, San Francisco.

The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's office at San Francisco.

UNITED STATES CON. G. & S. M. CO.—Jan. 19th. Location: Storey county, Nevada. Directors—James F. Brennan, Silas A. Stone, M. P. Madden, W. A. Woodward and John Sroufe. Capital stock, \$10,000,000.

GOLD GRAVEL M. CO.—Jan. 22d. Location: Mendocino county, Cal. Directors—S. C. Bugbee, W. S. Bell, Francis Cronin, H. J. Clarke and Madison Wheeler. Capital stock, \$1,000,000.

SILVER QUEEN M. CO.—Jan. 23d. Location: Pioneer district, Pinal county, Arizona. Trustees—W. R. De Fries, E. W. Bragan, H. A. Barney, G. W. Hopkins, W. H. Boothie. Capital, \$10,000,000, in 100,000 shares.

ASTOR M. CO.—Jan. 23d. Location: Elko county, Nevada. Trustees—George Muck, H. J. Sibley, M. P. Burnham, W. H. Simpson and E. A. Peck. Capital, \$10,000,000, in 100,000 shares.

CALIFORNIA CAR AND TRANSFER CO.—Jan. 23d. Object: To convey passengers, freight, express and mail matter to and from all parts of the city and county of San Francisco, also to and from any and all points and places in the States and Territories known as the Pacific coast. Principal place of business, San Francisco. Trustees—E. J. Baldwin, Joseph Sharon, Russell J. Wilson, Oliver Hinckley, M. G. Kennedy, P. J. Robinson, O. S. Carroll. Capital, \$4,000,000, in 40,000 shares. Capital actually subscribed, \$85,000.

NORTHERN KING M. CO.—Jan. 23d. Location: Arizona. Trustees—J. F. Clark, J. Wilson, M. L. Power, W. H. Lang and J. A. Holmes. Capital, \$10,000,000, in 100,000 shares.

ERSKINE CREEK M. CO.—Location: California. Trustees—E. R. Burke, H. H. Pearson, J. A. Pritchard and Jos. Clark. Capital, \$10,000,000, in 100,000 shares.

BLACK GOLD HILL M. CO.—Jan. 24th. Location: Amador county. Directors—John Beck, C. Remer, John Clements, R. W. Wallace and W. Westhoff. Capital stock, \$80,000.

The boilers at the Eureka Consolidated smelting works not now in use, are being overhauled and put in thorough working condition.

The death rate in this city for the past year was 16.8 in 1,000.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of mention:

BELT SHIPPING ATTACHMENT FOR PULLEYS.—R. Denmark, Washington Corners, [Alameda Co. It is often necessary in many kinds of mechanism (as for example the field engines or horse powers which are employed to drive threshing machines), to throw the driving belts entirely off the pulleys, and when those belts are large or tight, or the machine very heavy, it is very difficult to replace the belt on the pulley. The apparatus patented consists of a bar with a thin projection, which lies upon the outside of the pulley, and an arm that projects beneath the rim as far as the line of the spokes. A short pin passes through this bar, so that it crosses the slot formed between the two parts of the bar which clasps the rim of the pulley. A notch is made in the edge of the pulley, and when the bar is slipped upon the pulley the arm will rest behind a spoke of the wheel, and the pin referred to will fit into the notch to form a fulcrum and prevent the bar from being pulled from its place by the drag of the belt. The bar then projects at right angles with the plane of the pulley's motion, from the rim of the wheel, and all that will be necessary to slip the belt upon the pulley will be to bring it over the arm and set the engine in motion. The arm will run the belt into its place at once, and as soon as it arrives at the point where the belt leaves the pulley in its passage to the other pulley, the arm will be free to fall off, which it does, and leaves no dangerous projection, as would be the case if it were a permanent attachment to the wheel.

EGG HATCHER.—Walter Masterton, Stockton. Before incubation begins, and during several days after it has begun, the germ of the future bird lies on the top of the egg; for this reason the inventor applies the heat to the top of the eggs and maintains a lower temperature at the bottom of them. Air is necessary to incubation and passes freely through the pores in the shell of the egg during the process, and therefore a current of air is caused to circulate among them continually. A current of hot air in passing through the eggs and out into the atmosphere continually, will either destroy the vitality by excessive evaporation, or else impair it to such a degree that the birds will be feeble and few of them will live till maturity. To prevent this the inventor moistens the air with vapor of water before it mingles with the eggs. Notwithstanding the moist air constantly about the eggs, evaporation actually takes place and tends to stick the soft parts of the eggs to the shells. To prevent this and for the further purpose of bringing the germ into contact with as large a portion of the egg as possible during the early part of incubation, the eggs are turned over once a day. The patented arrangement of the several parts of the apparatus are intended to accomplish these general purposes.

REFRIGERATOR.—John W. Stewart, S. F. This patent covers certain improvements in the construction and arrangement of such structures as are used for storing and preserving by refrigeration such perishable articles as fruits, vegetables, meats, etc. The improvement consists in the construction of an air chamber with a main refrigerating chamber and one or more surrounding chambers or passages in such a manner that an automatic circulation of cold air will be maintained through the chambers and passages, the temperature of which will vary according to the distance the passage is situated from the main refrigerating chamber. By the peculiarities patented of a concentric arrangement of air passages by which is produced a continuous current of air and a consequent variety of temperature, fruits, etc., can be accommodated to the most natural temperature. In this single structure the inventor combines the elements of a refrigerating process adapted to all varieties and kinds of perishable articles.

Items of Interest from the Mines.

We give below items of interest from prominent mines, most of which are collated from letters of the respective superintendents on file at the offices in this city. Considerable of this news is later than that procured from the interior journals:

The 1900-foot level, north drift, in the Hale & Norcross, which connects with the Savage mine, is now partly cleaned out. The Savage company are running south in this drift to meet the Hale & Norcross miners. The latter will then connect and get a good supply of air. They can then remove the cave in the incline and lower the water, which is now 21 feet below the 1900-foot level.

The Eureka Consolidated dumps are full of ore, none having been hauled for several days on account of snow.

The Justice mine shows great improvement on several levels and is producing its usual amount of uniform grade ore.

They have gained 241 feet on the water in the Savage mine since they commenced pumping.

In the Leopard mine work in the 400 and 600-foot levels is progressing very favorably. There is every prospect of reaching ore in both levels

before the middle of February. Mill is running all right.

The heavy flow of water in the G. & C. shaft prevented any sinking being done a few days this week.

The lower levels of the Consolidated Virginia are much cooler, owing to the cold weather and the enlargement of the 1550-foot drift, connecting with the C. & C. shaft. It will yet require 10 or 15 days to complete the work of enlarging this drift.

In the Belmont everything about the mine is looking first-rate. The ore bodies are likely to prove extensive.

They are opening a new station 750 feet below the 400-foot level of the Utah.

The new pumping engine of the Overman has been started up and is working well.

The west drift on the 11th level of the Raymond & Ely is showing considerable improvement, and the formation at that point looks well enough to make ore at any moment.

The Knickerbocker Mining Company.

The annual election of the above company held last week, it was supposed it would be hotly contested, as two parties were earnest in their efforts to secure control. While the examination of the proxies was being made, Gen. H. A. Cobb, the President, made a verbal report of how he had been called to the presidency, of the corporation through the request of Mr. J. E. de la Montagne (since deceased) last August. And that during the whole period of his holding his office he had been harassed by vexatious litigation against the company and its Trustees. This litigation not only had an evil influence upon the stock, but by the suspension of work in the mine some damage had been done, and that great injury had been inflicted by this stoppage of prospecting. He was pleased to say that work had been resumed, the vexatious litigation ended, and the mine free from debt. For further particulars he referred the stockholders to the Superintendent's and Secretary's reports.

The successful party cast 57,486 votes and elected Gen. H. A. Cobb, E. C. Evertsen, James H. Crossman, J. M. Miner and Samuel L. Theller trustees for the ensuing year. The opposition having withdrawn, there was no other ticket in the field. Resolutions ratifying all actions of the trustees for the past year, and thanking them for the able management of the company's affairs during its most perilous period, were passed.

After the meeting adjourned, General H. A. Cobb stated to the stockholders that he would attend to their interests to the best of his ability, and he hoped that those who had lately been the opponents of the present officers would forget forever their former hostility and join hands with him and his friends in placing this stock at the rates it really was worth, which is in the neighborhood of five or six dollars per share.

Superintendent's Report.

At the time of the last annual meeting, we were much troubled by the flow of water in the face of the main drift of 400 level, and which which was not got under control until March 4th, when the work of sinking the drift was resumed and continued vigorously until the 27th of May, at which time the shaft had attained a depth of 862 feet, and the drift on the 700 level a length of 500 feet. At this date the Trustees, in consequence of the protracted litigation, ordered the suspension of work. In order to protect the work already done, a substantial bulkhead was erected on the 400-foot level, to hold the water back. The machinery was also protected from any damage. On the 28th of December last, litigation having apparently ceased, preparations to resume work were made. Upon examination, the machinery was found to be in good order, with the exception of the wire cable, but which has since been repaired. At the mine there are two 40-horse power engines, and one 80-horse. The Superintendent is confident that the mine will be cleared of water within two weeks, when sinking will be resumed. The dip and formation of the ledge on the 400 level show that it will be cut by the shaft within the next 100 feet. It costs about \$8,000 per month to extract the water, but when this is accomplished, the monthly expenses can be decreased. The mine has been opened to the inspection of stockholders at all times, and the amount of work done and the cost of the same will compare favorably with any other mine on the Comstock lode.

Secretary's Report.

The report of the secretary for the year was as follows:

RECEIPTS.	
Cash on hand Dec. 31st, 1875.	\$ 7,501 85
Assessment No. 14.	24,000 00
Assessment No. 15.	24,000 00
Assessment No. 16 (part).	25,074 20
Sundry sources.	1,725 00
Total.	\$80,301 05
DISBURSEMENTS.	
Expenses at mine.	\$ 5,661 98
Interest account.	689 65
Insurance.	1,000 00
Mining supplies.	16,939 97
Labor account.	18,642 24
Hoisting works (repairs).	2,608 91
Bank of California (Gold Hill).	8,642 00
Estate of J. E. De La Montagne.	10,724 05
Expense account.	9,550 20
Cash on hand.	2,883 12
Senator Mining Co.	2,760 00
Sundries.	5,738 93
Total.	\$80,301 05

The surplus over the liabilities is estimated at \$114,143.18. The indebtedness of the mine is \$2,573.43.

Raymond & Ely Mine.

The annual meeting of the Raymond & Ely mine was held on Tuesday last, and the following trustees were elected: M. L. McDonald, M. J. McDonald, T. C. Banks, C. G. DeCrao and R. H. Minister.

The following statements taken from the reports of the officers will show the financial doings and condition of the company and the operations at the mine:

Receipts.

From balances last fiscal year (since liquidation).	\$162,549
Bullion yield.	673,991
Property sales.	11,138
Ore sales.	25,355
Sale of mine supplies.	1,471
Sale of mill supplies.	1,224
Nevada Central Railroad.	449
Machine shop and foundry.	3,090
Balance assessment No. 5.	6,630
Account assessment No. 6.	340
Total.	\$788,257

Disbursements.

For balance fiscal report since liquidated.	\$140,023
For mine properties.	22,267
For mining.	858,029
For milling.	154,460
For miscellaneous.	115,736
For railroad.	4,750
Total.	\$795,265

The indebtedness of the company is \$11,302, and the cash on hand amounts to \$2,293.

The following denotes the total expenditures, including dividends, and the receipts of the company since its incorporation:

Receipts.

Total net profit of bullion yield.	\$4,564,414
From Pioche Phoenix Mining Company.	2,560
From assessments 1 to 5, inclusive.	510,000
From current liabilities.	22,780
Total.	\$5,099,654

Disbursements.

Mine properties.	\$1,144,654
Construction mining works.	134,325
Construction reduction works.	170,127
Nevada Central Railroad.	258,989
Mining pumps.	254,659
Dividends.	3,075,000
Current resources.	60,930
Total.	\$5,099,654

During the past year there has been extracted 8,167½ tons of ore, 8,467½ tons shipped to the mills and 8,842 4-5 tons crushed, which yielded \$62 per ton, 67 2-10 per cent. of the assay value. There were 97 tons of ore too base to be reduced by mill process, forwarded to the Sacramento smelting works, and the returns were greatly in excess of all expenses. A great number of feet of drifts and cross-cuts were run, but nothing of any permanent value developed. Several exploring cross-cuts and winzes were run at intervals along the line of the vein on the eighth level, but no ore of practical value was disclosed. The raise being carried up from the eighth level, 1,520 feet west of the main shaft, and which was furnishing some good ore at the last report, gradually died out in barren vein matter. On the ninth level, 700 feet west of the main shaft, a raise carried up 73 feet disclosed a well-defined vein carrying ore, but it proved too low a grade to be profitable for extraction.

From the 10th of February to the latter part of July the pumps were kept running constantly and they just succeeded in holding the water in check. Since August by a series of accidents the pumps have been compelled to suspend operations and have remained so until date on account of the non-completion of the gear wheels. During the year there were 6,702 lineal feet of drifts run and winzes sunk. For the lack of ore the company's 30-stamp mill has been idle the most of the year, and the company's 20-stamp mill was idle the whole of that period.

Black Hills Items.

At an informal session of the Dakota Legislature held at Yankton on the 20th inst., to listen to the address made by parties representing the interests of the people in the Black hills, concerning their resources, interests and wants, Professor Hencke presented an accurate map of the entire mining region, made from actual surveys, and showing the location of all the chief claims, accompanied with statistics as to their richness. Gen. Dawson, a revenue officer located there, and William Myer, publisher of a paper, also made addresses. The latter is on his way to Washington to urge legislation there. The statements were all unqualified as to the richness in mineral wealth, quality of soil and extent of timber. The Legislature awaits the action of Congress in ratifying the agreement of the Sioux commissioners, to provide settlers with courts and local organizations, but can do nothing until the Indian title is thus extinguished.

An express is to be put on between Custer and Last Chance district, in the Black hills. The miners of Harney district have adopted a local rule allowing the wives of miners actually in the hills to hold claims. Some of these feminine claims are very valuable, and the Montanians who hold the ground are determined to fight for the women's rights, while a number of recent comers are bent on "shooting" if a different arrangement is not made before spring.

The diggings of Battle creek are far superior to those of Deadwood. The snow prevents prospecting, but miners are on the ground waiting to work their claims in the spring.

An old resident of the Black hills gives the following advice, through the Omaha Bee, to persons intending to go to the hills:

First—Do not go in the winter season. It is perilous. On the Sidney and also the Cheyenne

routes there are miles of plains where there is no wood. Fuel has to be transported. Then, in snow-storms these plains are terrific. Nothing can withstand the piercing winds which sweep over them. Ranches are 30 miles apart on the Sidney route. Loaded teams do not usually make more than 15 miles per day; will have to camp; and all I can say in this weather is, God help them.

Second.—Do not go in the early spring; then the Indians will be troublesome, and if the agency Indians are removed, some, at least, will shoot away from the main body and join Sitting Bull's forces. I am apprehensive that in the early spring the Indians will be more villainous than at any previous time.

When, however, grass comes, so the army can move, the Indians will recede; so I would advise, don't go until either the middle of May or the first of June; then affairs will be safe. And remember, whoever goes to the hills must expect a hard time, and not much sunshine after he gets there. There is room enough and gold enough for a great many people yet. Nothing is gained by undue haste.

General News Items.

SMALL-POX is raging in New Orleans.

It is now announced that definite arrangements have been made with Moody and Sankey to come to California.

DURING the past year 212 lives, and 27 vessels, valued at \$150,000, have been lost from the Gloucester (Mass.) fishing fleet.

H. C. BENNETT, the defaulting pension agent of this city, has been sentenced to pay a fine of \$5,000 or go to jail for two years.

It is expected the Treasury Department will soon make another call for the surrender of \$10,000,000 of United States bonds.

CHARLES COLLINS, chief engineer of the Lake Shore and Michigan Southern railroad, committed suicide at Cleveland, on Friday. It is supposed that the Ashtabula accident deranged his mind.

THE Times correspondent at Paris reports that the Austrian government has concluded a loan of 70,000,000 florins, gold, with various London, Vienna and Paris banks. This loan is the balance of 110,000,000 florins which the Reichstag authorized the Minister of Finance to raise.

THE lighthouse board gives notice that on and after February 1st, 1877, the second order of fixed white light will again be exhibited at Point Bonita, California, but from a less elevated portion, and about one-fourth of a mile nearer the point. The light should be seen in clear weather, from the deck of a vessel, 18 nautical miles.

THERE is a deep sensation throughout the Basque provinces in consequence of the promulgation of orders appointing the 1st of March as the date for the beginning of military conscription in each of the provinces. General Quesada remains at Vittoria. An army of 30,000 will support the civil authorities.

STRICT regulations have been issued in England concerning the importation of cattle, sheep and goats, from Germany, France and Belgium, consequent on the outbreak of the rinderpest. Denmark and the Netherlands will be added, unless the importation and transit of German beasts is prohibited.

THE Harbor Commissioners have resolved to number the San Francisco wharves, according to the New York system, and hereafter instead of being designated by the street at the foot of which they lie, they will be called "pier" one, two, etc. The system will begin with pier one at Black point, and thence along the water front southerly.

WOODWARD'S GARDENS embraces an Aquarium, Museum, Art Gallery, Conservatories, Tropical Houses, Menagerie, Seal Ponds and Skating Rink.

A CARD.

Pacific Iron Works, First and Fremont Sts., bet. Mission and Howard, San Francisco, Rankin, Brayton & Co.,

Manufacturers of Engines, Boilers, Marine and Stationary. Pumping, Hoisting and Mining Machinery, including Batteries, Amalgamating Pans and Settlers, Concentrators, Ore Feeders, Crushing Rolls and Rock Breakers. Also, Water Jacket Smelting Furnaces for reducing Lead, Silver and Copper Ores, Quicksilver Furnaces, Retorts and Condensers, Roasting and Chloridizing Furnaces, Sugar Mill Machinery, Water Wheels, etc., all of the latest and most improved construction. Agents for the Allen Engine Governor, Cook's Boiler Feeder and Heater, Buckminster Rock Drills and Air Compressors, Wheeler's Ore Breaker, etc.

GEO. W. FOGG, Supt.

Amusements.

GRAND OPERA HOUSE, Mission Street, near Third. Open every evening with first-class Dramatic Company. Box office open from 9 A. M. to 10 P. M. Doors open at half past seven. Commence at eight o'clock.

CALIFORNIA THEATER, Bush Street, above Kearny. Open every evening with the best Dramatic Company in the United States. Box office open from 9 A. M. to 10 P. M. Seats may be secured six days in advance. Doors open at half past seven.

Mining and Other Companies.

Aetna Tunnel Company.—Location of

principal place of business, San Francisco, California. Location of works, Alta City, Salt Lake County, Territory of Utah.

Notice is hereby given that at a meeting of the Board of Directors, held on the second day of January, A. D. 1877, an assessment (No. 1.) of three cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary, at the office of the company, Room 6, No. 420 California Street, San Francisco, Cal.

Any stock upon which the assessment shall remain unpaid on Monday, the 26th day of February, 1877, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 19th day of March, 1877, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

JAMES M. HAVEN, Secretary.

Office, Room 6, No. 420 California Street, San Francisco, California.

Great Blue Gravel Range Mining Com-

pany.—Location of principal place of business, San Francisco, State of California. Location of works, Placer County, State of California.

Notice is hereby given that at a meeting of the Directors, held on the 23rd day of December, 1876, an assessment (No. 7.) of Fifty Cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin to the Secretary, at the office of the company, Room 33 Merchants' Exchange, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid, on Monday, the 26th day of January, 1877, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Wednesday, the 14th day of February, 1877, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

W. BRYANT, Secretary.

Office, Room 33, Merchants' Exchange, California street, San Francisco, Cal.

Howland Tunnel Company.—Location of

principal place of business, San Francisco, California. Location of works, Alta City, Salt Lake County, Territory of Utah.

Notice is hereby given, that at a meeting of the Board of Directors, held on the second day of January, A. D. 1877, an assessment (No. 1.) of three cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary, at the office of the company, Room 6, No. 420 California Street, San Francisco, Cal.

Any stock upon which the assessment shall remain unpaid on Monday, the 26th day of February, 1877, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 19th day of March, 1877, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

JAMES M. HAVEN, Secretary.

Office, Room 6, No. 420 California Street, San Francisco, California.

Mariposa Land and Mining Company of

California.—Location of principal place of business, San Francisco, California. Location of works, Mariposa County, Cal.

Notice is hereby given, that at a meeting of the Board of Directors, held on the sixteenth day of January, 1877, an assessment (No. 3.) of one dollar per share was levied upon the capital stock of the corporation, payable immediately in United States currency, to the Secretary, at the office of the Company, Room 33, Nevada Block, No. 309 Montgomery Street, San Francisco, California, to the Assistant Secretary, at the office, No. 3 Nassau Street, New York, N. Y.

By order of the Board of Directors.

LEANDER LEAVITT, Secretary.

Office, Room 33, Nevada Block, No. 309 Montgomery Street, San Francisco, California.

Annual Meeting of the Sierra Iron Co.—

The Annual Meeting of the Stockholders of the Sierra Iron Company will be held on Saturday, the 27th day of January, A. D. 1877, at 2 o'clock P. M., at the office of the company, No. 10, Falkland Block, 318 Sansome Street, San Francisco, to elect Trustees.

CALEB T. FAY, Secretary.

San Francisco, January 13th, 1877.

Silver Sprout Mining Company.—Prin-

cipl place of business, San Francisco, State of California. Location of works, Kearsarge Mining District, Inyo County, State of California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the nineteenth day of December, 1876, an assessment of twenty cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary at the office of the company in San Francisco.

Any stock upon which this assessment shall remain unpaid on the fifteenth day of February, 1877, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Saturday, the fourth day of April, 1877, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

T. B. WINGARD, Secretary.

Office, Room 20, No. 328 Montgomery Street, San Francisco, Cal.

Iron and Machine Works.

PACIFIC ROLLING MILL COMPANY,

SAN FRANCISCO, CAL.

Established for the Manufacture of
RAILROAD AND OTHER IRON

Every Variety of Shafting,

Embracing ALL SIZES of
Steamboat Shafts, Cranks, Piston and Connecting Rods, Car and Locomotive Axles and Frames,

HAMMERED IRON OF EVERY DESCRIPTION AND SIZE.

Orders addressed to PACIFIC ROLLING MILL COMPANY, P. O. Box 2032, San Francisco, Cal., will receive prompt attention.
The highest price paid for Scrap Iron.

THE RISDON Iron and Locomotive Works,

INCORPORATED.....APRIL 30, 1868
CAPITAL.....\$1,000,000.

LOCATION OF WORKS:

Corner of Beale and Howard Streets,
SAN FRANCISCO.

Manufacturers of Steam Engines, Quartz and Flour Mill Machinery, Steam Boilers (Marine, Locomotive and Stationary), Marine Engines (High and Low Pressure). All kinds of light and heavy Castings at lowest prices. Cams and Tappets, with chilled faces, guaranteed 40 per cent. more durable than ordinary iron.

Directors:

Joseph Moore, Jesse Holladay, C. E. McLane,
Wm. Norris, Wm. H. Taylor, J. B. Haggin,
James D. Walker.

THE O'HARRA

CHLORIDIZING FURNACE

Guaranteed to Chloridize from 85 to 95 per cent. of any gold or silver ores that are not more profitable for smelting. Will also desulphurize ores and put them in proper shape for working in cupola furnaces.

Cost of Roasting and Chloridizing by this Process:

Two cords of wood at \$6.....\$12.00
Two firemen at \$4.....8.00
1,500 lbs of salt at 1¢.....22.50
Wear of shoes and power.....1.50

Cost for 15 tons.....\$44.00
Cost for one ton.....2.93¢

In a furnace of three or four times this capacity the cost is decreased by 20 per cent.

The furnace is now working successfully at the Poe Consolidated Co's mines, in the Peavine District. For further information, apply to

D. J. O'HARRA,
Reno, Nevada.

The Ingersoll Rock Drill

Is Extensively Used in the East and

TAKES THE PLACE OF ALL OTHERS,

Wherever introduced, because it can be run with less power, labor and repairs, and do more work than any other Drill in the market. It has but few parts, is easily handled, being light, and has AUTOMATIC FEED, which saves labor. WE ASK FOR TRIAL AGAINST ANY COMPETITOR. For particular information regarding Drills or Air Compressors, send for circular to

GREAT WESTERN SCROLL SAW CO.,
Leavenworth, Kansas.

PICKERING ENGINE GOVERNOR.

Vallejo Foundry, October 17th, 1876.

Messrs. NEVLAN & YOUNG, San Francisco.

Agents "Pickering Governors." Gents:—The 10 two-inch Improved Speed Adjusting Governors I bought of you this year for my patent Straw Burning Threshing Engines give splendid satisfaction. They far surpass for regularity of speed any Governor that I have ever seen, and I have seen all the best kinds; I have seen the main belt fly off the pulley several times this season while threshing, and the engineer did not discover it, so perfectly was the speed maintained, until he was told of it; this I consider something wonderful; I consider the Governor absolutely perfect, so far as speed is concerned. I bought and put on to one of my engines a Shive Governor, to see which was the best, and after one season's trial I have no hesitation in saying they are as far superior to the Shive or any other Governor that I have seen or used, as the Shive Governor is to the old Butterfly Valve Governor. I wish you would send me the lowest price that you can furnish 25 Governors for next season's engines.
Yours respectfully,
I. L. HEALD.

59 Nevada Block, S. F.

THE ASBESTOS PATENT FIBER COMPANY,

TWO MEDALS OF HONOR.

Of Philadelphia, offer for sale through their agent in
San Francisco,Asbestos Steam Packing, Asbestos
Boards and Asbestos Steam Joints,All manufactured from the pure utilized Asbestos Pat-
ent Fiber, and under patents granted to J. S. Rosen-
thal. The packing is in all sizes from one-quarter to
three inches in diameter, round, and free from all grit
or mineral matter. The non-utilized or crude Asbestos,
manufactured by some parties into packing, is impure
and gritty, liable to injure the piston rod and should
not be used. The packing made under the Rosenthal
patents is of pure utilized Asbestos fiber, and a very superior article and entirely different from the so-called Asbestos
packing heretofore offered for sale. It is compact in form, will not fuzz or disintegrate, and will wear much longer
than any other kind of packing. The indestructible, expanding, contracting and lubricating qualities of Asbestos
are now universally recognized, and packing made from it is peculiarly adapted for steam engines and pumps.

ASBESTOS PATENT FIBER BOARD.

This is the champion non-conductor, to prevent radiation of heat and condensation of steam, as covering for
marine, stationary, or locomotive boilers and pipes, and for lining wood-work, where exposed to great heat. It is
light, flexible, is not disturbed by vibration, and will not char or crumble. The sheets are 30 by 44 inches, of any
desired thickness, and are easily applied.

ASBESTOS PATENT FIBER STEAM JOINTS.

Indestructible by fire or water, expands and contracts in a desirable manner, adjusts itself to any rough point,
is cheaper than rubber, and in all respects a superior article. PURE ASBESTOS FIBER for packing steam gov-
ernors and other purposes. All these goods are extensively used in the Atlantic States and give general satisfaction.

Office of Amazon and Glasgow Mining Co.,

San Francisco, Nov. 25, 1876.

A. L. Fish & Co., Agents for Knowles' Patent Steam Pump,

Gents: After using many devices for pumping mines I must say the DOUBLE ACTING PLUNGER MINING PUMP (Knowles' Patent), bought some time since for the Amazon and Glasgow mines, is seemingly as near perfection as it is possible to be. We carry steam 500 feet to the pump, raising water 400 feet, which it does easily with 40 pounds of steam, without the slightest jar on the pipes, and is perfectly noiseless. Gravel cannot wear the cylinder, and it is by far the simplest, cheapest and most economical way I know of for draining mines. I would cheerfully recommend them. Yours truly,

A. Caldwell, Superintendent.

Thorne & DeHaven Drill.

Union Rock Drill.

We offer this as the least complicated and most durable Rock Drill yet introduced.

Agents for the NEW YORK BELTING AND PACKING CO.'S RUBBER TEST HOSE, expressly for Fire Engine use; manufactured by the oldest and most responsible manufactory in this country. A Canadian Portable Saw-Mill.

We give on this page some illustrations which will be interesting to readers in our lumbering counties. There was on exhibition at the Centennial a machine commonly known as the Canada saw-mill, which attracted much favorable notice both on account of the simplicity of its construction and the speed and accuracy with which it accomplished its work. It was designed by the Waterous Engine Company, of Brantford, Ontario, Canada, expressly for use in the extensive lumber districts of the Dominion, to saw up the timber in the localities where it is felled, and thus to save the trouble and the expense of the carriage or rafting of the logs to distant points; and being portable, it may readily be removed from an exhausted part of a forest to a new situation. The machine is also excellently adapted for employment in ship-yards, in most of which establishments in Nova Scotia and New Brunswick, we are informed, it has superseded whip sawing by hand.

The annexed engraving represents the mill as it appeared at work while on exhibition at the Santiago (Chile) exposition of 1875. The portable machine has a twenty-horse power engine, which, together with its boiler, is of such weight and of such construction that both boiler and engine may easily be loaded on trucks, when changing the position of the mill, without any disconnection being necessary; so that the labor of a skillful machinist is not required to readjust the mechanism. The saw mandrel, feed and gig work are compactly arranged in an iron frame, and can also be loaded and moved without being taken apart; so that, when resetting the mill, all that is necessary is to frame the foundation timbers previously used in the ground, set the mill on them, coupling the engine shaft and saw mandrel, lay the track, place the carriage on it, and the mill is then ready to start. The whole operation does not take more than from one to two days.

The boiler is supplied with sawdust grates, by means of which it is enabled to keep up a full supply of steam with no other fuel than pine sawdust and refuse edgings. It is also covered with hair felting and lagged with wood or sheet iron. The plates are of the best English material, and the heads are Lowmoor iron. Each boiler is subjected to 120 lbs. cold water pressure before shipment. The 20-horse power engine drives a 56-inch saw, which will, it is claimed, cut from 6,000 to 10,000 feet of lumber per day, or 1,000 feet of one-inch pine lumber in a single hour. The 25-horse power engine, which is usually employed in connection with a tubular stationary boiler, drives any size of saw up to 66 inches, and its capacity is said to be from 8,000 to 12,000 feet of lumber per day.

At the Chile exposition, the 20-horse power mill, we are informed, sawed and edged 1,060 feet of lumber in 40 minutes, vanquishing all competitors and gaining a medal and diploma. It has received the first premiums at 10 Canadian provincial exhibitions, besides a highly favorable report from the judges at the Centennial.

A Villainous Act.

Of all fiendish ways to revenge a fancied injury, or maliciously injure an enemy, setting fire to or blowing up property in which they are interested is the worst. Persons who resort to such measures should have no mercy shown to them whatever. In such cases they not only injure the persons against whom they wish to be revenged, but also innocent persons whose all may be invested in the property destroyed. The latest attempt in this direction was made last week on the Comstock, where some villain tried to destroy the hoisting works and shaft of the Consolidated Virginia mine.

A few days ago the main works of the Con. Virginia were fired in an out-of-the-way and

cocks leads through flumes down the canyon to a point near the pan-mill, so distant that the noise of escaping steam or water cannot be heard in the works. Had he not noticed the open cocks just as he did, the whole place would have been blown up. The effect of opening these blow-off valves is to let the water out of the boilers, and everybody knows what follows when such a thing occurs. By whomever done, this is certainly one of the most damnable of all deeds which have been chronicled for a long time. The C. & C. shaft works above ground, which were endangered by this most dastardly scheme, have cost the joint companies nearly a million of dollars. There are scores of men constantly employed in and about them. The lives of all these men and the destruction of all this valuable property was attempted merely to entail a financial loss upon the companies.

Now the closest watch has to be kept on all

Light in Mines.

Very few people have any adequate idea what a quantity of candles are annually consumed on this coast, the principal portion of which is used in the mines. Light is one of the most indispensable articles in a mine, and with us it is mainly furnished by candles, although in other countries they use oil or gas. The article commonly used is the stearine candle of an inferior quality. They are called adamantine candles, and have various other names, but in their composition they are nothing more or less than a tallow candle partly freed from some of the olein contained in tallow. Taking into account the price at which they are sold, and the relative light they produce, they are the most expensive illuminating material of anything in common use.

But beside the heavy expense of the mine owners in buying the candles, another and more serious consideration is to be taken into account, and that is the offensive and unhealthy smoke evolved by their consumption in mines which are not well ventilated. It is hard enough where men work ten hours out of 24 to be deprived in the daytime of natural light; but it is still worse that they should be deprived of pure air, by its being poisoned with such unfit material as enters into the combination of most of the candles used. If candles must be used none but the best should be purchased. There is really no economy in buying poor articles of any kind, and in the matter of candles this is particularly true, as those of inferior quality give an indifferent light, are quickly consumed, and at the same time vitiate the air. Mine owners should pay more attention to the health of their workmen in simple matters of this kind, for their men will always do more and better work if they find that the employees are trying to do the right thing by them.

ACCORDING to the figures of Mr. Valentine, of Wells, Fargo & Co.'s express, it is found first, that the aggregate bullion yield has been increased about 56% in five years; second, that the gold yield shows an increase of a little over 20% during the same interval; third, that the silver yield has been increased 104%.

A REVIVAL of the copper mining interests of Calaveras county is apparent, there being several parties who propose re-opening mines. The Calaveras Citizen says that some San Francisco capitalists are about making arrangements to haul 1,000 tons of ore from a mine near Seco to the railroad.

A DISPATCH from Cheyenne says that three men were overwhelmed and carried down the mountain near the Centennial mine by a snow slide. One of them, Thos. Hodgson, of Holland, Michigan, was killed. The avalanche was set in motion by the discharge of a blast in a prospect hole.

CANADIAN PORTABLE SAW MILL.

unfrequented corner of the basement story of the building, under the carpenter shop. The fire was set in a mass of inflammable stuff—old rope, waste, oily refuse and rubbish generally—where it was supposed it would gain uncontrollable headway before its discovery. But owing to the constant watchfulness exercised over every portion of the premises, and the ample and convenient appliances provided for use in case of fire, this apparent work of the incendiary was discovered while yet within control and was quickly extinguished. Less than five minutes' time would have placed the whole property in jeopardy, and probably would have destroyed buildings and machinery valued at hundreds of thousands of dollars.

The Virginia Chronicle says that on Monday morning the attempt at the destruction was renewed in another form. On this occasion villains sought the C. & C. shaft for their operations, and attempted to accomplish by explosion what they had failed to effect by the torch. Just after the whistle had blown, and the morning shift came on, the fireman found it impossible to fill his boilers. On a hurried investigation he found the blow-off valve of two sets of boilers open. The escape from these blow-off

the hoisting works and the mills belonging to the firm who are the largest owners in this property. It does not seem possible this act could have been incited by mere jealousy of some prosperous neighbors; nor does it seem possible that any one could have the temerity to attempt such a deed simply for the purpose of depreciating the stock. If dealing in stocks has brought even a few men to such a pass as that, it is a bad state of affairs. It may have been some villain who has suffered from the fall of stock and wanted to bring others to his level, or some workman who had been refused work. Whoever he was, he would have had short shrift had he been caught. The attempt almost matches that of Thomassen, the dynamite fiend. We have heard of such acts in a lawless country where "strikes" were going on, but in Nevada, where people are generally prosperous and labor is well paid, it is monstrous.

THE war in New Granada still continues, and gross outrages are being committed by the Liberals.

WILLIAM J. LAWRIE will report to this office at once.

CORRESPONDENCE.

Mines and Mills of Butte City, Montana.

[From our Traveling Correspondent.]

The town is named from a prominent butte in sight. It has grown to a population of about 800, chiefly within the past two years. The rapidity of its growth is attributable to the richness and extent of its mines, which cover an area of seven miles in length by about four in width on the western slope of the Rocky mountains, and extend easterly to within five miles of the summit. As the ascent is gradual they are usually accessible. The country rock is granite, the general course of veins east and west, dip south, and strike of ore bodies, so far as explored, to the west. The general character of the ore is quartz, carrying sulphides of silver, frequently rich and from \$5 to \$50 per ton in gold, many veins, however, containing carbonate and sulphide of lead, running from \$30 to upwards of \$100 per ton silver, besides two or three belts of copper, going all the way from 10 to 70%, the average of ore shipped to date being put at 42%, leaving a large body of low grade ore worth from 15 to 30%, that can be made available and valuable with further and more extensive facilities for concentration.

There appear to be two principal belts, each with its parallel veins and spurs, about equally divided by the large butte previously alluded to, the leading lode lying south being known as

The Black Chief,

Probably from the large proportion of manganese it carries. It has been located in claims of 1,500 feet each to the Burlington and other promising claims beyond, the distance of three miles west of the discovery claim, and varies in width from five to 75 feet, carrying in addition to the rich sulphides some bromide and chloride of silver, together with more or less of gray copper ore.

The first location of the Black Chief, as well as

The Travonia,

Lying a little further south (it is understood), was made by Mr. Wm. Farlin, to whom the credit is due for taking the initiatory steps towards the development of the silver mines as well as having given a new impulse to the operations in the district, being the first to erect a mill. Correct results as to the working of ore from the Black Chief (discovery claim) was not ascertained, but shipments from the Travonia to Newark, N. J., were reported at \$350 per ton. The first silver ore worked here was by Prof. Smith, a year ago last November. It was taken from

The Banker Lode,

In northern belt, the property of Messrs. Smith and Coughenour, which has milled ore as high as \$204 in silver, saying nothing of the gold it contained. It has never paid less than \$50 per ton. The fissure is four feet; the pay vein from one to two feet. Fifty tons taken out at the depth of 60 feet, without assorting, yielded \$80 per ton. One hundred tons are now on the dump, all of which will pay handsomely. Ground was first broken on the

La Plata Mine,

Northern belt, in September, 1875, since which time work has gone on uninterruptedly, with the exception of about four months. The first 30 feet of shaft, besides much lower grade ore, yielded 20 tons fit for shipment to Freiberg, giving an assay value there of \$376 per ton silver and \$155 in gold. The next 30 feet of ore, not so closely selected and worked at home, yielded about \$400 in gold and silver. The shaft has since been sunk to the depth of 80 feet and levels have been run each way 135 feet. A contract has been entered into with the Dexter mill to furnish 500 tons of second-class ore, of which 325 tons have been already delivered and worked, yielding \$125 in silver and \$45 in gold. The ore vein varies from two to four feet in width. It is looked upon as one of the leading mines of the district, having paid over and above all expenses for improvements and developments as much as \$5,000 to the share. Inclusive of ore on dump, it has produced \$120,000 in the gross. Messrs. Downs, Jones, Scott and Leary are the fortunate possessors of this valuable property.

The Lexington,

Same belt, owned by Mr. A. J. Davis, of Helena, four shafts of 50 feet each, 200 feet apart. Lode from 5½ to 15 feet wide, all carrying good ore, somewhat similar to that of the La Plata, and sufficiently rich to justify on the part of the proprietor the erection of a fine 10-stamp mill, wet crushing, provided with four of the Purvine pans, for the purpose, principally, of reducing it.

The Mount Moriah,

Just above Butte City, the property of Mr. A. Scott, has a three-foot vein of ore, said to have worked from \$80 to \$100 in silver, besides containing a little gold.

The Gray Eagle,

Porter & Co., has a five-foot vein of ore, that

gives assays in silver from \$60 to \$250 per ton, and probably from 20 to 25% copper.

The Buffalo,

Blaine & Co., shows a vein of from seven to ten feet, nearly all ore, free milling, and running unassorted from \$45 to \$75 in gold and silver.

The Alice (Rainbow Lode),

The property of Walker Brothers, Salt Lake City, is situated one and a half miles north of Butte City. It is opened by two shafts of 75 feet each, the east shaft exposing a vein of ore five feet thick and extending from wall to wall, and the west shaft from one foot to 18 inches of ore. Three different lots worked at the Dexter mill were represented by Mr. Marcus Daly, the Superintendent, to have milled \$50 in silver and \$12 in gold. The statement was afterwards found from the books of the mill to be considerably below the average. The prudent Superintendent has probably seen some of the evil effects arising from glowing descriptions and exaggerated accounts, and preferred to be on the safe side.

The Magna Charta,

On the same lode, has been sufficiently exposed by three shafts to show a large vein of similar ore and of about the same value. The Walker Brothers own an interest in this mine also, in connection with Messrs. Barnard & McCauseland, of Butte City.

The Frank Moulton,

On the same belt, was located two years ago. Ground was broken on it within the last 12 months, and a shaft sunk to the depth of 76 feet. Fifty tons taken from this (five by nine), and worked at the Dexter mill, gave an average for first class, \$150 per ton and for second class, \$95 in silver and gold. Levels are being run each way and the ore coming out is looking splendidly. It is the property of Messrs. Clark & Larabee, First National Bank, Deer Lodge.

The Acquisition Spur,

(Packard & Co.), of Salt Lake, averages from three to four feet, widening in spots to eight feet; has milled on the ground \$200 per ton, the best ore being shipped and sold through Walker Brothers, of Salt Lake. It is represented as having yielded in one year as much as \$75,000, and paying by way of dividend \$5,000 to the share.

The Late Acquisition,

(Leffler, Clark & Co.), shaft 35 feet, four feet from wall to wall and three feet of ore, one-half free milling and the other argentiferous galena, requiring smelting, and sampling \$36 per ton. A second shaft of 60 feet on a branch, carrying no lead, shows a two-foot vein, a portion of which contains some high grade gold and silver ore, milling \$200 per ton.

The Burlington Lode

Is three miles from Butte City, and on the southern belt. A location of 1,500 feet was made June, 1875, since which a segregation has been made. The eastern end, owned by Roubush & Young, has a shaft 20 feet and level 24 feet, this distance being stope out. The ore vein is five feet, free sulphide of silver, and mills \$100 in silver and \$4.50 in gold. The prospect was sufficiently encouraging to lead the proprietors to erect an eight-stamp mill—wet crushing—which was about ready to start up. It has been well put up by a much respected namesake, Mr. R. C. Knox, an experienced mill builder of the Territory.

What appeared to be an improvement was noticed here in the Purvine pan, and of this gentleman's devising and construction, consisting of a wooden cone in the center, to prevent the accumulation of the sand at that point.

The west end of the Burlington, owned by Gassert & Reading, has four shafts, the deepest 45 feet. The whole lode carries ore from two to five feet in width, that has milled from \$60 to \$150 per ton, silver, and from \$5 to \$6 in gold. Further west, Wicks & Crawford, not to mention other locations, are taking out ore, similar in character and value.

The Seymour,

In same vicinity, but on a different vein, is six feet between walls, with 18 inches of free milling ore. Some taken from near surface and shipped to your city, yielded \$150 per ton. At the depth of 50 feet some fine looking ore was being taken out, giving sample assays of \$200 in silver and gold. It is owned by McMinn & Gale.

The Moody, the Sankey and the Kossuth (Orr & Co.) are more or less developed—veins from 18 inches to three and a half feet reported as running from \$60 to \$150.

The Great Republic,

(Butcher, Talbot, and others) shaft 50 feet. From two and a half feet near surface the ore had widened to six feet at foot of shaft. It works, mill process, \$60 and upwards.

The Ringgold (McMinn & Gale) in same part of Independence district, was said to show an 18-inch vein of ore, running as high as \$175.

Returning to the Southern or Black Chief belt, is the Mountain Boy (Noyes and others), greatest depth 54 feet, two levels, each 100 feet, two feet of solid ore, sampling at foot of shaft \$120. Some sold going as high as \$257. It contains considerable manganese, and is said to be somewhat difficult to reduce.

The Gold Hill, near Rockett, Independence district, shaft 80 feet, levels each way 100 feet, has an average vein of two feet of good lively gold quartz. The results of 100 tons, worked in arastra, were very satisfactory to Messrs. Carver, Aldridge & Wolverson, the owners. On

the same belt, half mile east, the California has a 12-inch vein, \$100 silver ore. The Anna and the Franklin, on the same hill (Mineral) are said to run about the same, the former of 10-inch and latter from one to two feet wide.

The Copper Mines of Butte,

If more convenient to market, would not be long in attracting the attention of capital.

The Parrott (discovery claim), situated on the northern belt, has paid well. Messrs. Downs & Leary have sunk to the depth of 170 feet on the vein, which varies from a few inches to four feet, the ore shipped running from 34 to 50½% copper, and about \$30 in silver.

The Parrott, No. 1, (W. J. Parks) has attained a depth of 160 feet, ore vein 1½ feet, average for first class upwards of 40%, second class after concentration running 45%. The ore is sold on the dump at \$55 per ton, leaving a margin for fair profits.

The Mountain has a shaft of 110 feet, and vein 3 to 8 feet of 35 per cent. ore, consisting of red and black oxides, black sulphurets and copper glance, with considerable silver. There are 1,200 tons of second class on dump that can be made equal to the first class by concentration, taking from 1½ to 2 tons of the former to make one of the latter.

The Alex. Scott (Belk, et. al.), shaft 100 feet—6 feet from wall to wall, and from 12 to 18 inches of ore, running 18% copper. As it gives in silver from \$75 to \$236 (assays) it should have been classed among the silver leads of the district.

The Colusa (Clark, Leffler and others) at the depth of 20 feet showed good ore, which was followed down 23 feet. The width of vein not ascertained, as no cross-cut had been made, but thought to be large, as the surface showed a width of 18 feet. Some ore shipped to Baltimore ran 32%.

The Adelaide (Carpenter & Ransom) has a four-foot fissure at the depth of 20 feet, with one foot of 30% ore.

The Hattie Harvey (Ransom, Owsly & Co.) shaft 70 feet, and two levels. The 45-foot level has been extended 100 feet, and the 70-foot level about 70 feet in length, exposing from two to six feet of solid ore, estimated to average 28%; from 200 to 300 tons on dump; 31 sacks assorted (copper glance) and sold to first National Bank, Helena, sampled 59%.

Something more of the mills, etc., of Butte before closing.

The Centennial Mill

Has been leased by Messrs. Manning (Foster and Ray), & Co., and put in good shape for successful running, having been constructed for treating base as well as free milling ores. There are four barrels in place (capacity one ton each), for treating ores somewhat after the old Mexican method, which has proved very successful here, as it is thought that the ores near the surface can be made to yield by this process 80% or upwards.

For the base metals a double reverberatory furnace has been constructed. The manganese ores are the most difficult to treat, and roasting seems to succeed better than any other process tried. After roasting, the ore is amalgamated in one of the Purvine pans, an invention of Mr. Wm. Purvine, a resident of the Territory, a full description of which cannot now be given, as he probably has not yet applied, as intended, through your agency for a patent. This much, however, may be said in its praise on the authority of Mr. S. H. Manning, the Superintendent. He states that this pan, when lined with copper and worked after the Mexican method, gives better results than any other he had ever used. It is the intention of the company hereafter to use iron in the pan for amalgamating the roasted ores.

In addition to the Centennial mill, the Davis and that of Roubush & Young, all of which have been briefly alluded to, there is also

The Dexter,

Dry crushing, of 10 stamps, at present run by Mr. W. A. Clark, of Deer Lodge, and under the immediate charge of his brother, J. K. Clark, to whom I am indebted for much valuable information, particularly in verifying statements in regard to the value of the ores in the district. The mill has a capacity of from 10 to 12 tons, and is supplied with four reverberatory furnaces, two combination pans, two settlers, agitator, retort, laboratory, etc., complete. The Washoe process was first tried, giving only about 60%.

At present the chlorination is used, showing a percentage of chloridized silver, (95%) and a saving in pan from 80 to 85%.

The average yield of 1,000 tons worked the last four months of the year, was \$150 per ton, which was much above some former runs. Of other improvements and facilities for reducing ores in the district, there are from four to five arastras.

Concentrating works chiefly for copper ores, operated by Mr. G. S. Olin, who uses the German automatic jig, in connection with Cornish rolls, screens for sizing and the usual appliances; lixiviation works (experimental) by Captain Turner, from whom you may have some account in future, and a neat little foundry and machine shop, run by Mr. J. F. Allen, who supplies the mills with their castings, and turns out the usual work of similar establishments. From the length of this letter, with many notes necessarily rejected, the reader can take it for granted that Butte City is one of the liveliest if not the liveliest camp in the Territory.

Tybo Mines and Reduction Works.

[Correspondence MINING AND SCIENTIFIC PRESS.]

Operations of the White Rotary Furnace.

Not since the inauguration of the great industry which has elevated Nevada to the greatness which she now enjoys, has there been exhibited in mining and metallurgical operations, and among the people generally, in every section from which we hear, so many gratifying evidences of progressive prosperity as there is at the present writing. From every quarter where mining constitutes the chief pursuit, are borne to us the glad tidings of improvement and development.

The close of the Centennial year has marked a new epoch in the career of the Silver State. The enormous yield of that memorable cycle has again revived public interest in the wonderful resources of her mines, in her limitless wealth of the precious metals, in her commercial progression, and in the affluence, comfort and social well-being which the spread of her agricultural and grazing interests have brought to her 52,000 inhabitants. This, it must be accorded, is a sparse population for a State like Nevada. It must, however, be remembered that her physical characteristics and climatic changes are not of the sort that are calculated to inspire a person with the desire to make it his future home. But notwithstanding the absence of the sylvan beauties, crystal brooks and diversified scenery, that add such a charm to life in our sister State across the western Sierras, we are every day acquiring fresh accession to our population; for where there is a foundation for prosperity, prosperity and population will surely exist. No doubt there have been many severe disappointments met with in Nevada, by incautious speculators. There has too much suffering resulted from stock gambling, and from the stupendous frauds that have been and still are being remorselessly practiced upon the unwary by unconscionable stock sharps. But however great the misery that has resulted from these things, it is an undeniable fact that there is not in the American Union to-day another section which holds out better and safer inducements to cautious investors and intelligent enterprise than does eastern Nevada. The history of the world is the

History of Metallic Mining.

The ancients, who probably knew nothing of stock boards, "corners," "shorting" and such modern terms, dabbled in it centuries before the Christian era; and the adventurous Romans worked the mines of Hungary long prior to the time of Augustus. The old Spanish mines, too, discovered and opened by the Carthaginians long before they had signalized themselves on the plains of Sicily, are still worked with enormous profits. They yield of the Mexican mines is not inferior to-day to what it was in the days of Montezuma. So, too, with the South American mines, whose productive qualities are as little impaired now as they were when the fierce followers of Pizarro swept down upon the peaceful hamlets and smiling valleys of Peru. History shows that wherever silver mines have been opened they continue, with few exceptions, to be profitably worked. This is not wonderful, for there is no other business from which such enormous profits are obtained, and for permanent and rich returns, silver mining has no parallel in any other branch of industry. These facts are borne out by the magnificent exhibit made by

The Nevada Mines

For the year just passed. The whole of the Spanish American mines did not produce more than \$25,000,000 annually during the first years of the present century, while the Silver State alone has in 16 years increased the world's wealth more than \$300,000,000, or more than \$18,750,000 per annum. Of this stupendous amount the mines of eastern Nevada must have contributed not less than \$50,000,000, \$30,000,000 of which were doubtless produced by the Eureka district, during the seven years of its progressive existence—last year's yield being \$4,003,174.75. Six hundred thousand dollars of this sum were realized from the sale of lead alone, thus showing at a glance the importance of the base metal interests of the great east; and since it is noticeable that argentiferous mining is every day becoming more productive and more extended, it follows as a natural sequence that there will be a much larger revenue derived from this branch of industry in coming years than there has been in the past ones. The operations of the Tybo Consolidated company and the

Developments of the Tybo District

Illustrate the progress and spread of base metal mining. Although this district has scarcely divested itself of its infantile habiliments, its mines have produced nearly, if not quite, \$1,000,000 since active operations were inaugurated two and a half years ago. Were the property of this company located on the great mineral artery which courses beneath the giant shadows of Mount Davidson, the price of its securities would be found away up among the 30's and 40's and were it only situated in the

Continued on page 70.

MECHANICAL PROGRESS.

Heavy Work with Gun Metal.

Our brass-working readers will be interested to hear of something heavy in "gun metal" castings. It seems there are in Glasgow six steel plated corvettes building for the Admiralty, and there are, says the *Glasgow News*, other novelties of construction in addition to that involved in the use of steel rather than iron plates. Not the least interesting is that of the stems, all of which are formed of gun metal, instead of being forged of wrought iron, which has hitherto been the invariable practice in shipbuilding in iron. Although casting in brass or gun metal is an art that is quite unfamiliar to iron-founders, a firm of iron-founders were found quite willing to take the duty in hand. Their air furnace is of such an extraordinary capacity that it is capable of melting probably 35 tons of pig iron. The first of these stems was cast several weeks ago, and at the end of every fortnight that has since elapsed another has been turned out, No. 4 being cast on Tuesday. On each occasion there has been a large party of spectators present, owing to the great interest attaching to the casting of such extraordinary structures in a material with which the workmen had no practical acquaintance.

In outline, each of these stems bears some resemblance to the prow of the war galleys of the ancients. Continuous at one end with the keel of the vessel, of which it is to form a prominent feature, the stem bends forwards and upwards, becoming about 15 inches thick along the anterior border, and attaining to about four feet as its greatest breadth. It then curves backwards and upwards, gradually becoming smaller towards the upper end, where it merges into the bulwarks of the ship; indeed, it may be said to consist of two curved arms meeting in the broadest part at a somewhat obtuse angle, and there becoming a sort of ram. Speaking roughly, each stem may be said to be about 45 feet long, and as it is all cast in one piece, it is not surprising to learn that, in its finished state, the casting weighs about 10 tons, and that its production necessitates the employment of a charge of 14 to 15 tons of metal. The metal may really be regarded as the alloy known as gun metal, the essential ingredients of which are copper and tin. Consisting chiefly of old brass or bronze guns cast at Woolwich, the charging of the furnace commenced at half-past four o'clock on Tuesday morning. The first portion, weighing about seven and a half tons, and consisting of metal left from a former casting operation, and fresh copper and tin, was melted down by eight o'clock, when a fresh charge of about two tons was thrown in. That was melted down shortly before mid-day, and other two tons were charged in. At one o'clock another ton of old metal was thrown in. Next in order 10½ cwt. of tin were admitted—the whole being finished by two o'clock. Immediately before tapping a number of slabs of zinc or spelter, weighing about 1½ cwt., were cautiously slipped into the molten mass, and the whole well "rabblled." It was so arranged that the finished metal in the furnace should have something like the following composition: Copper, 16 ounces; tin, 1½ ounces; zinc, one-half ounce; the resulting alloy being guaranteed to stand a tensile strain of 15 tons per square inch. In all, about four tons weight of old guns were used in the production of the charge of fully 15 tons. At about half-past two o'clock, the metal, being perfectly liquid, was tapped into an oblong basin or reservoir, specially constructed of iron, and faced with loam for the reception of the material. When about eight tons of the charge had been accumulated, a shutter which was situated at the farther end, was raised by means of a lever, and the metal flowed into the mold through the "runner gates," of which there were upwards of 30. Fully half an hour elapsed before the metal in the deeper parts of the "runners" had lost its liquidity, thus differing very considerably from the iron which is so frequently the subject of manipulation in the same workshop. It may be worth while to mention, that in the construction of the mold used in casting these stems, upwards of 40 tons of ironwork are employed, and that the finished casting is valued at £1,000.

LECTURES TO ARTISANS.—An exchange says: Scientific lectures to the working men are a feature in England. They should be in this country. We are happy to learn that some of our intelligent manufacturers have not only subscribed to the wisdom of this idea in theory, but have grappled with its practical demonstration. Messrs. Chess, Smythe & Co., manufacturers of tacks and nails, Pittsburg, have appropriately fitted out a lecture room in their works, and the senior member of the firm has opened a course of lectures on mechanical science to their workmen. The North Chicago Rolling Mill Company, of this city, have encouraged, and aided the establishment of a library and reading-room for the benefit of their workmen, and each year subscribe for several copies of the leading industrial and scientific publications for the reading-room. If other proprietors of extensive manufacturing establishments would adopt the same course we presume they would find their reward in the growing intelligence and efficiency of their workmen. The old idea that the nearer the workman can be brought to an automaton—a human machine—the better, is fast being exploded and done away with. *Hardware Trade.*

Weakness in Iron Bridges.

The Ashtabula disaster is calling out notes from mechanics concerning the elements of weakness which exist in iron bridges. The following, which we find in an *Eastern exchange*, relates to this subject, and to the general subject of the strength and durability of bolts and the metal of which they are made:

During several years of instruction in bridge building and personal inspection of American and Continental viaducts and bridges, I have noticed two elements which affect the Howe truss, and all suspension systems other than those of wire—either of which would tend to an accident similar to the recent crash near Ashtabula. The first grows out of the simple principle that the screw is but the continuous inclined plane. Hence it has been repeatedly found that the strain upon vertical rods has worked the thread down and through the nut overhead; especially if the double nut has not been used and carefully inspected.

In the Polytechnic building of Wabash college, where the apparatus is elaborate, a flying swing once suddenly fell. The cables were attached to inch bolts, passing through heavy hemlock ties, and these were locked by cast iron washers and heavy nuts. An examination showed that other apparatus, gradually and by infinitesimal progress, had worked downward. This discovery has induced frequent inspection, almost always resulting in some slight correction. The fact that a nut seems tight upon application of the monkey wrench does not prove that this slow process has not begun. The oxidation of iron may check, but only suspends, the inevitable tendency of the rod to work down the thread of the screw. The tension is so great upon suspension rods that the test must be made by comparison with the original set of the nut. If it has moved up at all after the weight has been fully felt, it suggests investigation.

The other element is that of crystallization, which affects the fibrous texture of wrought iron as well as the more passive nature of cast iron. The cast iron, which fills the requirements of a column to resist compression, would be absurdly applied to the purposes of suspension; and yet the continual jar (not the strain) of suspension rods, under the passage of trains, destroys or changes the fibrous texture, and leaves a crystallized material of very moderate cohesive restraint. The late Edwin J. Peck, Esq., of Indianapolis, formerly President of the Indianapolis and Terre Haute Railroad Company, and of rare mechanical genius, had occasion to examine into the causes of the sudden fall of one of their bridges, of the Howe truss pattern. In spite of argument and discussion, he very quietly produced the upper ends of several suspension rods, showing that they were crystallized, and these broke under the hammer more easily than ordinary cast iron of the Indianapolis Iron Works.

The question of temperature enters into this inquiry, but with less force than in a matter where cast iron would be a substantial element to be considered. It is a fact that the best wrought iron or steel rails, which break during extreme cold, are more frequently broken by fast trains than by freight, or slow trains. The principle has been adverted to. It is the difference between a distributed and a concentrated force. A prostrate man with an anvil on his breast will receive the blow of a sledge hammer without sensation, and so does the slowly transmitted force spare a rail, a suspension rod, or bridge, which a sudden force would destroy.

FERRO-MANGANESE.—This metal, which has of late attracted considerable attention as a substitute for spiegeleisen in Bessemer steel manufacture, is made at the Terrenoire iron works, France, in the following manner: The manganese liquor produced in the manufacture of bleaching powder is precipitated by means of lime; the precipitated oxides are mixed with a necessary quantity of the purest iron ores (generally powdered magnetic ore from Algeria) and the mixture cemented together, after the addition of 15% of pure coal dust and a little flour spar, with bitumen. The bricks thus formed are heated in a furnace (four-dormant) preparatory to their being transferred still glowing into a Siemens furnace. The goal of the operation is the reduction of the metallic oxides and their fusion. Both operations demand an exceedingly high temperature, inasmuch as manganese is very difficult of reduction, and the carbon powder distributed throughout the bricks forms a notable hindrance to the uniform heating of the ore. In addition to these difficulties, the slag is a most difficultly fusible one, being highly basic; since the presence of silica in the operation is specially to be avoided. The manganese and iron ores employed must be free from sand and clay, and the hearth of the furnace must be formed of an agglomerate of graphite, the successful production of which has but lately been achieved. So soon as the attendant notices that the masses begin to fuse, he adds a certain quantity of spiegeleisen rich in manganese, and brings the charge to complete fusion. The product contains often as much as 65% of manganese. *—Deutsche Industrie.*

BOOK SHELF FITTINGS.—A contrivance for supporting shelves in bookcases, chemical cabinets, or elsewhere, has been patented by Tonks & Sons, of England. A flat strip of iron, three-quarter-inch wide, and stout enough to be firm when fixed, is pierced with openings at regular intervals to receive the neck of a loose stud which forms the support of the shelf. The cheek of the bookcase must of course be mortised to receive the plate, which lies flush with the wood.

The strips are fastened down to the wood by ordinary screws. The contrivance has been varied by having the strips stuck up so as to form a hollow behind, in which the neck of the stud is received. This arrangement permits the strips to be screwed on the uprights without mortising, the ends of the shelves being cut out to accommodate the patent fitting.

PRESERVING IRON.—A scientific discovery of importance to the iron industries in this country, has been made, says the *Sheffield Independent*, by Professor Baril, of the London University. The use of iron as a building material and for shipping purposes is greatly checked by its tendency to corrosion and rapid decay, through exposure to the weather, and all experiments for casting it with protective washes have proved useless. Professor Baril claims to have discovered a process of oxidizing iron, so as to prevent corrosion under any circumstances.

SCIENTIFIC PROGRESS.

Interesting Experiments in Diffusion.

Professor Sir William Thomson, the eminent English scientist, recently lectured in Glasgow on the "Diffusion of Liquids and Gases." After alluding to the diffusion of fluids by endosmosis, the lecturer proceeded to illustrate the diffusion of liquids without any septum intervening. The point which he desired especially to bring out was the marvelous slowness of this process in the case of liquids, and its rapidity in the case of gases. To show this he exhibited the results as far as they had gone, of two secular experiments on the diffusion of liquids. He had filled on the 29th of November, 1870, and the 14th of December of the same year, two long tubes, the lower half with water and the upper half with alcohol, colored red with cadbear, and had then hermetically sealed them. He pointed out to what a comparatively small extent diffusion had taken place during six years, as indicated by the extension of the cloudy stratum of colored liquid downwards into the colorless water. In passing, the lecturer mentioned that a neater and more satisfactory form of the experiment would be to enclose the liquids in a prismatic tube, so that they might be separately identified by their different powers of refracting light. He also drew special attention to the considerable amount of shrinkage which occurred as the process of diffusion went on. In one of the tubes this shrinkage was .70 in. and the other .67 in. during the six years in which the experiment had continued. This matter of shrinkage from diffusion of liquids of different density was one, as far as he was aware, not touched in the text-books. After adverting to the length of time which would elapse before the experiment would be completed, Sir William stated that he had in the university laboratory experiments in process, which, instead of "secular" might be called "millennial," as perhaps 2,000 years would be required for their completion. He had filled two great tubes, 25 feet in length, one with colored water and alcohol, and another with solution of sulphate of copper and water. At the bottom of the latter tube he had placed crystals of the salt, so that the lower portion of the solution would be kept in a state of continual complete saturation. The lecturer next proceeded to point out that, marvellously slow as the process of the diffusion of liquids was, if they were left to the unaided action of the natural law of diffusion, it was very easy so to expedite the process, that the work of centuries might be done in half a minute. This was effected by simply reversing the tube several times, so as to bring the particles of the two liquids into contact. If this were done very slowly it was possible that by the heavier fluid flowing under the lighter, they might change places in the tube without much visible diffusion. But the repetition of the operation brought about complete diffusion, and the total amount of shrinkage could then be measured. Sir William next adverted to the process of diffusion of gases, and showed, by a modification of Graham's experiment of diffusion through a porous septum, how extremely rapid the process is. He pointed out that, according to the Kinetic theory, the difference depended upon the nearness to each other of the ultimate molecules, or atoms of the liquid, as compared with the mutual distance of the molecules of the gas. In the latter case the molecules had the utmost facility of motion, which those of the liquid had not. As illustrative of this point the lecturer took the hypothetical case of a field of sheep, the individual members of the flock being uninfluenced by any consideration but that of going about the field to graze. At the commencement the sheep in one-half the field were branded red, and those in the other black. The diffusion of the red sheep among the black would follow a fixed law, and the extent of it at different intervals of time would be a matter of statistics—an actuary could calculate it. The rate of diffusion would depend very materially on the number of sheep in a given space. If closely packed, like the molecules of water, the diffusion would be slow; if so wide as to have perfect freedom of motion, like the molecules of gases, then it would be proportionately rapid. Sir William concluded by referring to the diffusion of gases through liquids, and, in this connection, adverted to the now well-known experiments of Dr. Fergus, in reference to the passage of sewer gas through drain traps.

The New Pink Coral Reef.

Lieutenant Commander Gorrings, of the United States steamer *Gettysburg*, under date of December 15th, 1876, reports to the Secretary of the Navy concerning the recently-discovered coral bank as follows: We reached the vicinity of the bank on Tuesday morning, December 12th. Soundings taken on and near the bank indicate that it is the summit of an isolated submarine elevation which rises regularly from a general depth of 2,200 to 2,700 fathoms. Within a radius of 20 miles from the position of our anchorage the summit—on which there is less than 100 fathoms—is of irregular shape, about seven in greatest extent north-northeast and south-southwest and five miles in breadth. Outside of this limit the depth increases towards the northeast and southwest to over 300 fathoms in about three miles, and at about the same rate to 1,000 fathoms at a distance of ten miles. Towards the northwest and southeast the increase appears to be much more rapid, a depth of 2,750 fathoms having been found at a distance of 20 miles in the former direction, and 2,200 fathoms at 13 miles to the northward. There appears to have been some violent disturbance at the bottom within a comparatively recent time, as coral obtained from depths of 50 to 250 fathoms is broken into fine pieces of rock, and mixed with small pebbles and pieces of sand and shells. That obtained at less depth is alive, although apparently but a comparatively short time at work. There is manifestly no connection whatever between this bank and that discovered by the *Josephine*. The Secretary of the Navy has decided to give to the coral bank discovered the name of Gorrings bank, in honor of the discoverer.

Laboratory Notes.

T. A. Edison, in an article in the *American Chemist*, has the following laboratory notes, which are of much interest, and may be found valuable:

Hard rubber or vulcanite, placed for several weeks in nitro-benzol, becomes soft and pliable like leather, and easily broken.

The vapor of chloral hydrate is a solvent of cellulose. I have found the corks of bottles containing the crystals eaten away to the depth of a quarter of an inch, the cork being resolved into a black semi-liquid. Certain kinds of tissue paper are partially dissolved in time, if thrown in a bottle containing the crystals.

A very difficult substance to dissolve is gum copal. I have found that aniline oil dissolves it with great facility.

Hypsulphite of soda is apparently soluble to a considerable extent in spirits of turpentine. Large crystals of "hypos" melt down to a liquid after several weeks, and if the bottle be shaken, partially disappear. The turpentine smell nearly disappears.

The vapors of iodine, in the course of several months, will penetrate deeply into lumps of beeswax.

If to a solution of bisulphide of carbon there be added twice its bulk of potassium hydrate in sticks, and the bottle be well sealed, the whole will, in two months, become an intense reddish, syrupy liquid, with scarcely any free bisulphide of carbon.

THE MICROSCOPE IN GOOD HANDS.—A competent judge declares that Professor Pasteur has saved enough to France by his discoveries to pay the entire indemnity to Germany. He is a great chemist, and one of the most skillful experimenters in the world. For many years he has been subjecting the theory of spontaneous generation to the most severe scientific tests, and is positive in his conviction that all life, so far as we know it, springs from living seed or germs. The experience of the best dealers in wine has been baffled in seeking a remedy for a difficulty. Professor Pasteur put some of the spoiled wine under the microscope and soon discovered the cause of the trouble. Minute organisms were found in the wine in every instance, and the change of quality was due to their presence and growth. Of course they grew from germs, and if the germs could be destroyed the mischief would be averted. Judging from experiments in other liquids that heat would be fatal to the germs, he subjected the wines to a degree of heat which they could bear without injury, and found that all the germs were destroyed. The wine makers profit by the science of the chemist, and save millions of dollars formerly lost by the spoiling of the wines. Having been successful in making wines unalterable, he turned his attention to vinegar. This was subject to changes, which made it putrid and worthless. He detected another kind of organism in vinegar, and taught the dealers how to destroy it in germ and keep the vinegar unharmed.

NATURAL GAS.—There are now three gas-producing wells at Beaver Falls, Pa., one of which has been in operation over 17 years. Two of the wells are nearly 1,100 feet in depth, one having been reamed out, and is said to produce about 100,000 feet per day, which is utilized in the cutlery works, except what is used in the gas-lighting works, where it supplies about 60% of what is used. The other well is to be bored out to eight inches. The third well is recently bored and struck a good vein of gas at 500 feet. This well is to be cased 12 inches, with a small tube inside to continue the boring to a greater depth, while the present product of gas, which is much greater than the other wells, can be utilized. *—Coal Trade Journal.*

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR.

MONTICHRIST.—*Amador Ledger*, Jan. 27: We regret to learn that the entire force of men was discharged from this mine on Sunday last, with the exception of one man retained for the hoisting of water. It is difficult to ascertain the precise reasons which led to this move. According to the Superintendent's report, the last crushing of rock averaged between \$10 and \$15 per ton, which, with economical management, ought certainly to leave a handsome profit after paying expenses. The managers of the mine assert that the closing down of the mine is for the purpose of straightening the books of the company, so as to ascertain definitely how matters stand. The stoppage is only temporary.

MACE'S MILL.—Mace's mill, beyond Volcano, which has been running steadily through the fall until the late spell of weather, has suspended operations until spring.

QUARTZ MINING BEYOND VOLCANO.—The owners of the small quartz claims a few miles above Volcano continue to work the same with gratifying results. Stoken is putting his mine in order for a good run in the spring. Griesback is taking out rock, ready for shipment as soon as the roads will allow. In fact, all the mines are looking well, with every prospect of making their owners wealthy in the future.

EAST KEYSTONE.—This mine is located at Amador City, being the eastern extension of the Keystone ledge. It has lately been incorporated into 70,000 shares. A shaft is down 30 feet, with a two-foot ledge of fine ribbon rock at the bottom. The ore is expected to mill from \$20 to \$30 per ton.

TALISMAN.—In running the tunnel to connect the air shaft with the main shaft, the miners struck a splendid body of ore on Saturday last. We have not seen specimens of this rock, but those who have informed us that it is literally covered with gold, estimated to yield \$1 to the pound. We have not heard the size of the ledge. The mill is still a long way from completion, the delay being occasioned by the difficulty in getting the iron work ready.

ONIDA.—Everything around the Onida mine looks thrifty and prosperous. Sufficient rock is taken from the lower levels to keep the 60-stamp mill constantly running, and within the past few weeks a marked improvement has been noticeable in the quality of the rock. Mr. Robinson, the Superintendent, has put things in excellent shape. The water supply used to be conducted through ditches to the mill, resulting in considerable surface water draining into the mine. These ditches have been discontinued, and an immense stock of firewood is on hand, enough to supply the furnaces for months to come.

FIDDLERTOWN GRAVEL CLAIMS.—The supply of water is at present inadequate to start all the large gravel mines around Fiddletown. The big company have commenced work upon one of their claims. A number of San Francisco men have visited Fiddletown of late and invested in the mines.

BUTTE BASIN.—James Morgan, of San Francisco, has been in Jackson the last few days. The object of his coming is to start mining operations at Butte Basin. A very rich streak of gravel was worked at this place years ago, and it is thought by some that the pay dirt goes deep into the earth, in the shape of a basin. To test that theory is the object of the present undertaking.

BUTTE.

BIG BAR MINING CLAIM.—Oroville *Mercury*, Jan. 26: On the second day of January a company consisting of Chas. Waldeyer, G. W. Dyer, J. C. Logan, D. K. Perkins, J. M. Brock, J. J. Smith, J. M. Burt, E. W. Fogg, Mr. Fitts, B. P. Hutchinson and three others whose names have been escaped us, bought what is known as the Grange boys claim, on the North fork, paying therefor the sum of \$10,000, half down and the balance some time in the fall. The company have incorporated and are known as the Big Bar hydraulic gravel company. Several of them are among the best miners on the coast. Mr. Waldeyer owns the richest mines in the county, and is probably the wealthiest man in the county in this line. Mr. Dyer is the foreman of the Spring Valley company. Others of the company are also skilled in mining, and all seem to feel that they have purchased a good piece of property. They have opened up a good road to the mine at a cost of \$1,200. They are now building 1,200 feet of flume, and will soon have it completed and ready for use. As the North fork is a very rapid stream, wire cable will be strung from bank to bank, and everything taken across the river on a car suspended from the rope or cable. It will cost some \$3,500 to put the claim in working order, but it is fast being done under the direction of skilled men, and by the first of March we shall be able to give our readers a more correct idea of the richness of the claim than at present.

CALAVERAS.

MILL STARTED.—*Calaveras Chronicle*, Jan. 27: The new mill at the Tiger mine, Rich Gulch flat, was started Thursday morning last. The battery contains 10 stamps and is run by steam. We understand that the machinery performed satisfactorily upon its initiatory trial, everything running smoothly. As there is a considerable quantity of quartz in the dumps, we presume the stamps have been set to work at crushing it. The Tiger is one of the most promising mines in this vicinity.

UPPER COUNTRY NOTES.—Very rich rock has lately been discovered in the Carey mine near West Point. The mill being put upon the Carey is nearly completed. At the Champion mine a new sinking shaft is just finished and running smoothly. As there is a looking as well as ever, which is the most complimentary remark that could be made respecting it. Fields & Co. are taking out good rock. Reports from the Mina Rica continue favorable, work progressing steadily and with good results.

WASHINGTON.—Mr. William Devan, who during the fall made extensive preparations for mining out his premises on East Center street, formerly occupied as a Chinese garden, has commenced washing. Mr. Devan has every thing in first-rate shape for washing, and having the advantage of an abundance of water, will run off gravel rapidly. At present ground sluicing is the method of washing employed. Work is being energetically urged forward day and night, and as we hear very favorable reports concerning the richness of the gravel, there is no question but that Mr. Devan will make the enterprise pay handsomely.

MOUNT TOLU.—Everything is progressing favorably at the Mount Tolu mine, Jesus Maria district. The dumps are so full of rock that the mining of ore has been suspended until the stamps "catch up." Something like 200 tons of quartz is now in readiness to be crushed, the battery of five stamps being unable to work the rock as fast as a small force takes it from the mine. At the depth of 80 feet the chute of pay rock is over 100 feet wide, averaging about three feet wide. The prospects that the Mount Tolu will develop into a permanent, paying mine are flattering.

MINING JOBS.—At the Duryea claim, Chile gulch, labor is progressing effectively. The mining of gravel is completed and unintercepted, and the battery is kept in motion day and night. A large amount of gravel is put under the stamps daily. The tunnel being run in the Brown claim, Tunnel ridge, is lengthening rapidly. Still in bedrock, Veith, the great hydraulicist, is running powder drills. Preparations are also being made for putting up a water-power derrick. The foundation is being laid and it is expected to have the machinery in operation in a week or two. For some time past Mr. S. Moser has been engaged in opening his hydraulic on Tunnel ridge. Preparations are now nearly completed. The flume is laid and everything will be in readiness to commence piping soon. Emerson, proprietor of the Happy Valley claim, has resumed washing. All the improvements contemplated are

completed, and the mine is the best appointed one in the county. Piping is being vigorously prosecuted—a large head of water being used—and operations systematically and perseveringly urged forward. Piping is steadily going on in Cook's new hydraulic in the vicinity of the French hospital. We have not yet found time to visit the claim and consequently cannot give details. Work is also progressing steadily in Cook & Co.'s claim on the Calaveras, with uniformly good results. There is now an abundance of water all around, and mining operations generally are being energetically pressed.

INYO.

DEFIANCE.—*Cons Mining News*, Jan. 27: P. Reddy, Esq., Superintendent, and John S. Gorman, Foreman of the Defiance furnace, went below last Sunday on business connected with the company. On returning it is thought matters will be so arranged that the Defiance mine and furnaces will be started on a solid basis and for an extended run.

MODOC CON. M. Co.—This company's mines in Lookout district are turning out their usual quantity of rich bullion and are looking as well as ever at all points. Ten men are employed taking out ore for the two furnaces. The ore is being taken from Confidence Nos. 3 and 4, and Lookout. On the Lookout they are sinking on the ore body of the same strike, about 30 feet south from the old winze. If this ore continues to show, as is now indicated, it will be of immense value. The two mines, Confidence No. 4 are very fine, but of a drier nature, rather more of a milling character. By mixing the ores of No. 4 with those of No. 3, very high grade bullion is produced, going from \$450 to \$600, some shipments being made as high as \$600 per ton in silver. Three prospect tunnels are being driven in different directions, deeper into the hill.

FURNACE NO. 1 has been running uninterruptedly for the past 45 days, under the able management of Mr. J. J. Williams, who is entitled to much credit for the very successful manner in which both furnaces have been run, particularly since so many experts came up here to examine the ores and gave it as their opinion that they could not be melted. Mr. Williams, however, finds it so long filled with satisfaction to the company and credit to himself, to accept another offer elsewhere. T. H. Selby, a nephew of the late Thos. Selby, has arrived and taken the place of Mr. Williams. He has had the reputation of being an excellent smelter, and the interests of the company will probably not suffer by the change, though all are not so successful as Mr. Williams as could be desired. Mr. Polkenhorn, the mine Foreman, is also entitled to the warmest consideration of the Modoc company for the very able manner in which he has prosecuted work in all the mines for development of splendid ore bodies now in sight.

TUS WOOD and coal road to Wild Rose canyon, from whence those supplies will hereafter be obtained, is now completed and in excellent condition. A tramway from the furnaces to connect with the Wild Rose road has been commenced, and machinery will be ordered immediately. It will be an iron double track T-rail tramway, with a heavy stationary engine to propel the cars.

ACUM AND AROENTUM.—This is a company lately incorporated, and we are assured the men composing the same are wealthy and mean business. Mr. T. A. Brawley has been appointed Superintendent. He arrived here last Tuesday, and at once commenced work on the company's mines, which are situated in Minute-Gun canyon, through which the road hence to Lookout runs.

LOS ANGELES.

COAL IN THE ARROYO SECO.—*Los Angeles Herald*, Jan. 29: We were shown yesterday a very fine specimen of coal from a mine which is now being opened on Mr. Prudent's land, in the Arroyo Seco. It is a large block, and the quality is excellent. The prospect was covered by a Mr. Carson, a son of the celebrated geologist, philosopher and friend of Gen. John C. Fremont. He has run a tunnel into the hillside to a depth of 40 feet, and he thinks he will strike a fine vein of coal when he gets in a distance of 80 feet. He is now showing his faith by his works, because he is doing all the labor at his own expense. He is confident, on being assured that Mr. Carson believed in the existence of a reliable coal mine, agreed to give him one-half of the coal product if his expectations should be realized. Mr. C. has been at the entire outlay for the work himself, and is confident that the results will be satisfactory.

NEVADA.

ALLISON RANCH PHENIX MINE.—*Grass Valley Union*, Jan. 26: A company has recently been incorporated for the purpose of working the above named mine. The location is near and to the west of the old Allison Ranch mine, and the veins are almost parallel. The "Phenix" as the ledge has always been called up to the time of the recent incorporation, has never failed to give large results whenever a crushing from it has been made, and number of times the ore has been taken from the mine, and sold at points, have been made. The ledge has not been constantly worked because the owner, Mr. Patrick Hennessey, did not have the required capital for that purpose. Steam machinery for pumping is absolutely necessary there in order to get down more than 30 or 40 feet. That difficulty has now been arranged for, and the Allison Ranch Phenix shaft will soon be worth money. We regard this as about the best of the returning good results to owners as any untried venture in the district. We are familiar with the history of the Phenix and its record is most excellent. The most of the stock of the new company is owned in Sacramento. Mr. Hennessey will superintend the mine.

SPARROWHAWK MINE.—This is a prospecting operation now going forward in Woodpecker ravine near this town. It is being conducted by workmen and the results have so far been satisfactory. A tunnel has been opened, and the ledge has been cut so as to give about 60 feet of backs. Only about eight tons of ore have been taken out, and of this a trial working of four tons has been made by mill process. The four tons yielded six ounces of retorted gold. The ledge is from eight to 14 inches in thickness. The showing is so good that systematic work, in the regular Grass Valley style, will be continued in time.

AMERICAN.—*Transvaal*, Jan. 26: The American mine, Juan, has been a good producer, and has gold enough in it yet to make the owners regular "mildons." From 1863 to 1872 the company's books show that \$1,241,240 was taken out. It is one of the best and most economically worked mines in the county. A tunnel was commenced about eight years ago and was completed last year. It is 400 feet in length, and will permit the ground to be washed through it. There is ground enough to last for 15 or 20 years. The mine has the most complete system of undercurrents to be found in the State, and but little gold is allowed to escape. We believe there are over 40 of these gold savers between the mine and creek. The owners are John McCoy, J. S. McBride, George C. Spooner, S. M. Hall, A. P. Swan, M. Dickinson, Furth Bros., and others. They are all first-class men, and deserve the prosperity they are enjoying.

THE Cold Spring company are now running three drifts in their claims. Two are run for the purpose of taking out gravel, and one is being pushed ahead through hard rock for the purpose of striking the main channel. In the gravel there is a large quantity of quartz rock, which the company have been mining and contains gold in paying quantities, and which has been hitherto thrown away. It is estimated that the whole of it will pay, on an average, \$20 to the ton. It comes out with the gravel and is easily saved. It will add greatly to the proceeds of the mine when in full operation. The company think at least five tons per day of it can be taken out with the gravel. Since the gravel is being taken out, it has been learned, was once crushed at Kitz's mill, and yielded \$35 to the ton.

SAN BENITO.

CON. RAUSTON.—*San Benito Enterprise*, Jan. 27: The above mine, or combination of mines, is located about one mile south of the Clayton furnace. The owners are J. A. Owens, C. W. Wentworth, T. H. Swain, W. Eppeimer and Thos. Conlan. Four hands, old miners, have been driving two tunnels on it since last fall, and have just completed their first contract. In the main tunnel, which is about 60 feet, they struck a heavy body of metal, and

the indications are that the Ralston will turn out one of the best mines in the Coast range. The men who done this work on the mine have had sufficient confidence in the prospect as to take their pay altogether in the stock of the company, and consider that they have made a good bargain. A new contract will be let to the same parties at once. A quantity of specimens, taken from the mine in the principal tunnel, is on exhibition at Justice Owen's Court room, and according to the judgment of some experienced "quartz sharps" they contain silver and gold, as well as quicksilver and other metals. There is hardly room to doubt that the mine will turn out to be valuable.

TRINITY.

NORTH FORK.—*Trinity Journal*, Jan. 27: Chris. Meekel, who was in town this week, informed us that the old town of "Bagdad" was just as dull as any other place in the county and nothing short of plenty of water could be expected to enliven it. From him we learned further that the McAllister company are working some very rich ground near the site of the old mill on the other side of the river. The new ground is extensive and under Mr. Burns's energetic management the company will probably realize a profit this season.

RUSH CREEK.—This is rather an agricultural than a mining country—only one company of white men working on this side of the river. That is the Chamberlain Bros.; when they are making money or not, I cannot say, but they certainly deserve to, as they are hard working, industrious men. Paulsen & Christiansen turned the water into their pipe across, or rather under the river, on New Years day, and it works splendidly. Two Chinese companies are working with the water, and a third will soon start. Mr. Muncey to-day presented me with a piece of rock from his claim on Deadwood, a little the richest I ever saw in any part of the State. Mr. Muncey informs me that it works about the same as the Deadwood. I had almost forgotten to say something about the Buckley ditch, as neat and well dug ditch as the State affords. It is now completed from Bol's hill to Van Matre creek, a distance of 23 miles and I understand will be completed to Stuart fork the coming summer.

TUOLUMNE.

BRINO REOPENED.—*Tuolumne Independent*: The old Monteruma tunnel, after a lapse of about 17 years is about to be reopened by a company of San Francisco gentlemen, under the management of John H. Neale, an experienced miner both in gravel and quartz. The tunnel is situated about two miles below Rawhide, and was owned in 1859-60 by Stranahan & Dann. A difficulty arose about this time between the owners of this claim and a man named McAllister, on account of the former parties tapping a spring and draining the water from the latter's ranch, and culminated in the death of McAllister by the hands of Dann. The claim has ever since lain idle, and up to the time of the difficulty paid well.

FEELS.—In our last we stated that the ditch to the Cave diggings was taken from the Tuolumne river. We were wrong; it is not, but is taken from one of its tributaries. The two new and Buckley drills at the Solsby mine are now on the ground, and they will be in operation as soon as possible. They will be worked by steam power, and a 60-horse power engine will be used for that purpose. They will be used in running a new drift from the south to the north shaft, and with the ample motive power provided, will greatly facilitate the work. The West Wall vein claim, owned by Glasson & Co., parallel with the Solsby lead, big and fair to be a really good deposit of precious ores. The vein in the present bottom of this mine looks like a rich and permanent deposit of galena, iron sulphates and gold, and a *fac-simile* of the Solsby upper tunnels; and there is not a doubt but that, as it is further opened, it will spread a large amount of money in circulation in this county.

Nevada.

WASHOE DISTRICT.

SINIERA NEVADA.—*Gold Hill News*, Jan. 31: The flow of water at the bottom of the shaft is still very strong, but is easily handled by the pumps. The face of the north drift on the 1700-ft level is developing some fine quartz and low grade ore.

CROWN POINT.—Sinking the main incline is making the best of headway, the rock in the bottom blasting out well. It is now down to within about ten feet of the 2000-ft level. As soon as a sufficient depth is attained the 2000 level station will be opened, and a drift started to prospect the ore vein at that point.

HOMESTEAD.—Sinking the new shaft has progressed at a very satisfactory rate. Considerable clay and occasional bunches of quartz are met with. The old prospecting operations of the company demonstrated the existence of good ore deposits at no great depth, and this new shaft is intended to open the mine properly and give an outlet to its riches.

SAVOGE.—A breakage of a pump rod during the first part of the week caused a stoppage which permitted the water in the shaft to rise to a distance so great as to stop all work in the main south drifts on the 1900-ft level. The broken rod has been replaced, however, so that everything is again in the best of working order.

TRINITY.—The main incline has reached the 1830-ft level, at which point a station is being opened. In the meantime a winze is being sunk below the 1700-ft level to prospect the vein in the downward direction.

SILVER HILL.—The main incline has been sunk during the past week 123 feet. The rock in the bottom is very firm and the flow of water is gradually lessening.

CALEDONIA.—The shaft has reached the 1440-ft level, at which point a large working station is being opened, and large tanks erected preparatory to letting in another of the heavy lift pumps. At the same time preparations are being made to cross-cut and determine the value of the ledge on the 1200-ft level.

MEXICAN.—The ore prospects in the drifts on both the 1600 and 1700-ft levels are gradually on the increase.

SUCCESS.—Sinking the main shaft is making the best of headway. The new pumping machinery is working finely.

NEW YORK.—The excavation of the third or pump compartment to the shaft is pushing ahead as usual, in hard rock.

COSMOPOLITAN.—The usual yield of ore comes from the upper stopes, and also from the north drift from the incline below the main adit level.

SILVER TUNNEL.—Total length of tunnel, 14,780 feet. Somewhat softer material has been met with in the face of the header during the week, allowing of better progress.

LADY BRYAN.—The new and powerful engine is in place, together with its accompanying machinery, and will be ready to start in about two weeks, draining the water from the mine. The newly encountered last week, and will be forwarded from San Francisco at once, together with the balance of the hoisting machinery. The mine has now passed into the possession of men of known probity and ability, with plenty of capital and energy, and they show a disposition to develop and run the mine upon its own real and acknowledged merit. At the earliest period practicable the new machinery will be completed and set in motion. A new battery put into the mill of the company, and the extraction of milling ore from the mine begun.

CON. VIRGINIA.—Daily yield, 285 tons of ore, keeping the Consolidated mill steadily running. On the 1500-ft level the spur of ore recently struck is 28 feet in width, and will mill about \$100 per ton. On the 1500-ft level the hanging and foot veins are now connecting with each other, and the Gould & Curry is nearly completed. On the 1200-ft level the main south drift connecting with the Gould & Curry is being enlarged and repaired as rapidly as the nature of the work will permit. This is being done to get at and extract the ores now known to exist in that portion of the mine. The west drift from the C. & C. shaft has passed through the foot vein, and is now connecting with the Gould & Curry in first-class ore. This streak of porphyry was something very similar to that found on the east side of the ledge on the 1500-ft level.

JULIA.—The main cross-cut on the 1800-ft level from the

south drift is making the best of progress. This drift after penetrating the quartz and ore recently struck a distance of 90 feet, passed into a horse of porphyry 30 feet or more in thickness. This porphyry has been passed through and the face of the drift is again in quartz and ore of a better character than any that has yet been struck. The vein at that point is undoubtedly wide, and the quartz shows a decided improvement with every step of progress made. The south drift which was recently started on the east body of ore, is making good progress, the face in solid quartz of the finest character.

WELLS-PAROE.—The work of development in this mine will be pushed forward hereafter with renewed energy, and under more favorable auspices, the company being reorganized with more effective plans for the future.

IMPERIAL CON.—The north drift from the bottom of the south winze on the 2135-ft level is making steady progress, the face still in a very favorable vein formation. Both the north and south drifts from the bottom of the north winze on the same level are being pushed rapidly forward, the face of each in ledge material.

OVERMAN.—Sinking the winze below the 1200-ft level is making good progress, with increasing prospects. The prospecting drifts on the 1300-ft level are making the best of progress, the water having been pretty well drained at that point. The pumps continue to work admirably, and water is being taken with perfect ease. The connection of the south drift on the 1200-ft level with the north drift from the Caledonia mine is fast cooling off.

BECKER.—Daily yield, 130 tons of ore, keeping the Santiago mill crushing to its full capacity. Sinking the main incline is making the best of progress. Sinking the drain shaft is also making good headway, notwithstanding a strike, strong flow of water at the bottom. The 1800-ft station is completed and drifts have been started to open and prospect the ore vein at that point.

CHOLLAR-POTOSI.—Sinking the Combination shaft is making good headway, the bottom in good working order. The new pumping machinery is all in the best of working order, whenever there is need of it.

HALE & NORCROSS.—Owing to a breakage of a pump rod in the shaft during the first part of the week, the water rose rapidly to a considerable distance above the 1900-ft station, the pumps unable being unable to keep it down. The Savage break, however, has been fully repaired, and both pumps running in conjunction with one another, are again rapidly gaining on the flow. The water is now down to its old status, below the 1900-ft station.

TRUMAN.—The ore dump has been filled with ore, and a new dump has been provided until the weather will permit of the ore being hauled to the mills. The stopes on the 350-ft level are looking splendidly. A winze has been started downward on the ore body, which is also looking finely.

CALIFORNIA.—Daily yield, 500 tons of ore, keeping the mills crushing to their full capacities. The ore breasts and stopes are showing well at every point. The north drift on the 1400-ft level, is being enlarged. The south drift from the winze, on the 1850-ft level, is steadily though slowly advancing, the face in excellent ore. Sinking the C. & U. shaft has made but very slow progress during the week, owing to the steady and fearfully strong flow of water at the bottom.

LEVATHAN.—The foot-wall of the new ore vein in the north drift is showing around more to the northward and is being followed. The vein continues to the east end of the drift, and the main body of ore is being left to the east end of the drift. At some favorable point farther north another cross-cut will be made into or through the ore vein.

GOULD & CURRY.—The south drift on the 1700-ft level is being pushed rapidly ahead. The east cross-drift on the same level has been stopped, and diamond drills substituted. While these drills are being used, work in the winze below the 1700-ft level is suspended, on account of not having sufficient air with which to drive the machinery of both places.

JUSTICE.—Daily yield, 360 tons of ore, keeping the mills all steadily running. Another mill, the Atlas, has been added to the reduction force. The ore stopes on the 400, 600 and 700-ft levels show but little change. The developments on the 800-ft level continue of the most favorable description.

YELLOW JACKET.—Both of the two east cross-cuts on the 2040-ft level are being driven forward, the face of each drift showing a decided improvement for the past two days. These two cross-cuts are located between the north and south drift.

BULLION.—The north and south drifts on the 1500-ft level of the Bullion are both making excellent headway, with steadily increasing prospects of ore. The main east drift, on the 1600-ft level, appears to be just entering the vein, and is also looking very promising.

DAYTON.—The east drift on the 700-ft level is showing better with every foot the drift advances. The north drift on the 220-ft level is also showing some very fine ore. The company have over 800 feet of entirely unprospected ground north of the old works, which gives room for some good ledge developments.

KOSUTSI.—The west cross-cut on the 600-ft level is in 30 feet, the face in broken quartz and porphyry. This drift is gradually draining the flow of water, and it is confidently believed that when the white portion of the vein is developed a paying mine will be opened.

NORTH CON. VIRGINIA.—Preparations for draining a heavy flow of water, should any be encountered on the 1100-ft level, by means of diamond drills, has nearly been completed. The new pump station at the 1150-ft level is about finished.

LADY WASHINGTON.—The north drift is in 138 feet, and during the past two or three days has run into a heavy body of hard, compact quartz, the whole of which is the drift being in it. It gives good assays, and is a very encouraging prospect.

BALTIMORE AND AMERICAN FLAT.—Sinking the north winze below the 1050-ft level is making the usual fair rate of progress. The north drift on that level is showing some fine streaks of ore.

DIAMOND CON.—Sinking the winze on the ore vein below the 1300-ft level is making excellent progress.

PHIL. SHERIDAN.—Sinking the shaft is being pushed ahead with the usual vigor, the bottom in splendid blasting ground.

SOUTH COMSTOCK.—Drift north from the main east drift at the 300-ft level is to-day in 34 feet and still in low grade ore. Some streaks of this, however, give high assays.

BUEY.—The ore stopes north of the winze on the 350-ft level are looking well, and are yielding the usual quantity of milling ore. The Hope mill is kept steadily running on ore from the mine.

FLORIDA.—Sinking the main shaft is being pushed ahead vigorously, the bottom in porphyry.

MINT.—Sinking the main shaft is making the best of headway, the bottom in good blasting ground. The flow of water gives no trouble.

SUPERIOR.—The shaft is now draining out rapidly.

ALTA.—The pump station is completed and sinking the main shaft has been resumed.

Utah.

NOVELTY MILL.—*Salt Lake Tribune*, Jan. 23: Messrs. Harris and Tischer have moved the Novelty mill from Orr, and it is now on the way to Leeds, where the owners expect to have it in operation within four or five weeks. It is a five stamp mill. They pretend to be able to work ore to within 5% of the fire assay value by the leaching process. An exceedingly rich strike has been made in the Kearsarge mine on Shoo Fly hill in Dry canyon. Two young men who had been employed at the Mono, leased the Kearsarge for four months from the first of January, contracting to do certain work on the mine for four-fifths of the ore extracted. On last Thursday evening a vein of horn silver ore between three and four feet thick ran the bottom of the mine, the whole of which were sent to this city to be assayed. A piece given to Mr. McVicker went \$18,000 in silver and \$24,000 in gold, or \$42,000 to the ton. Another specimen, assayed by Mr. Frank Foote, went \$195.95 in gold, and \$14,800.08 in silver to the ton.

Continued from page 66.

midst of the Eureka bonanzas \$1,000,000 would be a small price for its 50,000 shares. The corporation is a close one, consequently its members hold their stock pretty tightly and care not to sell it, well knowing that they could not very readily find a better, safer or more permanent investment than they possess in both the mines and reduction works of Tybo. The latter comprise two furnaces and a 20-stamp mill, which are kept continuously employed in the make of bullion—one of the former has been taken down to make room for one of larger capacity. This will be completed by the end of this month. The united reduction capacity of mill and furnaces then will be from 85 to 90 tons each 24 hours. The company's mines are in a flourishing condition, every quarter of the underground workings of the lode exhibiting an abundance of finely graded smelting and milling ores.

The Mill

Is now running on ore from the company's mines very successfully, thus attesting both the value and importance of the White rotary oxidizing furnace and rotary drier as auxiliary reduction agents. These have been in constant use since the 4th ult., and it is enough to say that they have thus far performed their work in a manner to win the approbation of all who have witnessed their operations and that they will subserve the purposes for which they were constructed is now no longer a question of doubt, but an assured fact, as the annexed data will abundantly prove. The chlorinization of the ores is very thoroughly effected in their passage through the superheated cylinder. They are chloridized up to 90 and 92% of their assay value, and the contractor, Mr. G. O. Kilbourne, hopes ultimately to obtain 95%, which perhaps would be the highest percentage that has ever been obtained by millmen on the coast. The

White Rotary Oxidizing Furnace

And rotary ore drier, were erected here last November in connection with the company's mill. They were constructed under the immediate supervision of Geo. O. Kilbourne, Superintendent of the Jefferson mine, in this county. He claims that the plan on which the fire-places are constructed and arranged, and the manner in which the fires are controlled, together with the chloridizing chambers into which the pulp is discharged after passing through the flames of the cylinder, are original, and entirely different from anything that has heretofore been introduced for the purpose of chloridizing base ores. The

Rotary Drier

Is a unique apparatus, and its completeness and fuel-saving qualities should bring it into general use for drying ores for the battery, and since it is conceded to be far ahead of the old metal-plated drying kilns, there is little doubt but it soon will supersede the latter.

The ore when fed to the rock-breaker is discharged directly into the head of the drying cylinders, whose dimensions are as follows: Length, 17 feet 6 inches, outside diameter, 36 inches, inside, lined with strong corrugated iron, cast in sections to fit the sections of the cylinder. This, bolted together, is placed on a substantial foundation composed of stone and hewn timbers, having an inclination of one-half inch to the foot, or eight and three-quarter inches altogether. The ore, as already stated, being fed at the upper end, is met by the heat and flames from the fire maintained at the opposite end. After passing through the cylinder, which makes about nine revolutions a minute, the ore is discharged into an iron spout, placed at a proper angle in the brick, between the bridge or fire-wall and the end of the cylinder, thence falling directly in front of the battery caement to the feeder. One man on each shift will dry 30 tons per day, and use not more than a half a cord of wood, of the value of three dollars, thus making the cost of running rockbreaker and drying furnaces \$11 each 24 hours, or less than 40 cents per ton. The dimensions of the

Oxidizing Furnace

And method of handling or working it are as given below: Length of cylinder, 24 feet; outside diameter, 40 inches, inside lined with best of Scotch beveled firebrick. It is cast in four-foot sections, which are firmly bolted together and placed on a substantial foundation, having an angle of inclination of 9-16 of an inch to the foot, bevel geared and driven (not the foundation) by a six-inch belt, and rotates at the rate of nine revolutions per minute. It is both fed and fired at the same end, but by a peculiar arrangement of the fire space the man in charge is enabled to temper the heat and the draft to any required degree. This is a very important arrangement, for by its means there is promoted that sharp concentration of heat that is usually obtained in firing with the feed.

The pulp, after passing through the cylinder, and while discharging into the first chloridizing chamber, is caught by a sharp concentrated auxiliary fire, which thoroughly chloridizes every portion of the pulp not chloridized in the cylinder. There are four

Chloridizing Chambers.

The first is about nine feet high by four feet wide and nine feet long; the other three decrease each six inches in size from one to the other. Each chamber has a division or hanging wall, varying from three to two feet in height from the chamber floors, forming thereby short diving furs, so arranged that all the heat from both fires (head and end) passes along with the pulp while moving and close down on it when at rest, during the time it remains in the chambers,

which is from three to four hours.

The discharge or hauling doors of the chambers are nearly three feet above the cooling hearth, and so arranged that the red-hot pulp, as it is drawn out, is allowed (with occasional stirring) to remain on the hearth till cool enough to pass to the amalgamating pans.

The furnace, although now handling fully 30 tons of ore each 24 hours, consumes not quite two cords of wood, and the bullion demonstrates the equally agreeable fact that 90% of the assay value of the ores is obtained by this process. The pulp is conveyed from the battery to a large sized hopper, placed on a level with and a few feet from the furnace, by the usual method of revolving screens and hoisting buckets, placed on an endless belt. These buckets discharge their contents into said hopper, which is connected with the feeding and firing end of the cylinder by a revolving screen, which propels the pulp from the hopper to the feeding aperture of the furnace. Two men, one on each shift, are capable of attending to all the wants of the furnace, which, as is shown, is by no means an expensive concern to operate, everything being simplified and the whole constructed with a view to facilitate and cheapen the operations attending the roasting and handling of base ores.

Unverified Predictions.

When the company and its agent, Mr. Kilbourne, first determined to adopt the "White" process, and the improvements suggested by the latter, mentioned elsewhere, they were confidently told on the threshold of their undertaking, by chronic croakers, who themselves were never guilty of having achieved even an ephemeral success in any department of either mining or metallurgy, that the White furnace would not meet the requirements, that failure was inevitable, and that the pulp, instead of being chloridized, would cinder and mat before reaching the cooling hearth, or would roll up into huge balls in the furnace, etc., *ad nauseam*. These oracular utterances, however, have not been borne out, for the results are entirely different and are satisfactory to all concerned, thus proving that these leaden ores can be chloridized up to the necessary percentage to pay for working them, as shown by recent returns.

Cost of Construction, etc.

The remarkable success that has attended the operations so far cannot be otherwise than highly gratifying to both the company and the builder; for the enterprise and expenditure of the one and the skill and inventive genius of the other have been suitably rewarded by the fact of having demonstrated to the people of eastern Nevada that sulphureted ores are susceptible of profitable treatment by the White oxidizing furnace.

The cost of the whole apparatus, embracing ore drier, pulp furnace, belts, machinery, construction, etc., approximates \$25,000, and the cost of running, including the two essentials of labor and feed, does not exceed \$33 for each 24 hours employed. This latter feature is an all important consideration in a place like Tybo, where there is such an abundance of ores that do not carry sufficient lead to facilitate smelting, nor yet too much to prevent their being thoroughly and profitably worked by the White oxidizing furnace. GOTHAM.

Tybo, Nev., Jan. 18th, 1877.

"Vulcan Coal Mine," Santa Cruz County.

EDITORS PRESS:—Having promised to keep your readers informed in regard to all developments of the Vulcan coal mine, I will here state to you all that I have been able to learn of the work since performed and of the character of the coal as the new shaft has been sunk lower and the new vein has been opened on the line of its lateral extension.

The new shaft run down on the vein has reached the distance of 18 feet from the surface. The dip of the vein, which was first at an angle of 50 degrees, soon began to assume more of a perpendicular direction, leaving the vein with but a slight inclination to the south in its continued descent. After reaching this depth in the shaft a tunnel from the outside, 18 feet in length, was run from the road, at the foot of the hill, at an elevation of about 20 feet above the bed of the creek. Having connected the shaft and tunnel, drifts were then run in either direction on the vein. The coal has improved in quality in the shaft as the depth increased, until now it is uniform in character, and free from extraneous substances. At this depth also the vein is well defined. The lower wall is now composed of solid sandstone, lined within with about 3½ feet of slate, then the vein of four feet eight inches of solid coal, afterwards the upper wall of sand rock, black and discolored, for one and a half feet outside the coal. The drift extension to the east of the shaft is about eight feet in length, seven feet in height and in width of the thickness of the vein. The drift running westwardly is the same in its dimensions as the other, except in the thickness of the vein, which has diminished to about three feet.

About 12 tons of good coal had been taken from all these excavations at the time of our visit. The coal is what the miners call "blind" coal, and is similar to anthracite in character.

The company having become satisfied as to the genuineness of this vein, determined to continue the workings in the old tunnel, running northward from their 160-foot shaft. They have secured its perfect ventilation and they can now work in it without hindrance or danger.

Mr. Wm. Muller, who, after graduating from both French and German scientific mining schools, and a large experience in the mines of the Old World, came to Mexico, and for four years superintended in some of the best copper and silver mines of the New World, has now the superintendence of this coal mine. Mr. M. informed me that by continuing the present tunnel for about 50 feet further, and 300 feet from the shaft, he expected to strike a coal vein well defined in its croppings at the surface, and dipping at an angle which would intersect the tunnel at this depth and distance. Having succeeded in striking the vein and opening it well, he then proposes to return to the shaft and there extend the tunnel southward to about 50 feet, where he expects to strike at a right angle the new vein already opened and described as above. Then, again, he proposes to run a drift eastward 160 feet, with a slight ascent on the vein, towards the excavations already made on the vein. Then from the end of this drift, he will run an incline upwards, at an angle of 45°, a distance of 230 feet, to the present opening tunnel near the road. On this incline he proposes to work both ways: upwards and downwards. The coal taken from the tunnel and lower drift will be hoisted, of course, up the 160-foot shaft until the incline is completed; when all the coal from every part of the mine will be drawn up this incline, and the shaft only used to drain the mine of water. Mr. Muller also expects to intersect and pass through this coal vein (in the southward extension of the tunnel as described), on whose croppings the deep shaft was first sunk. He informed me that this vein at the surface was inclined northward, at an angle of 35°. At the depth of 85 feet from the surface a tunnel was run from the shaft northward until the vein was intersected. At this point it was found to be broken and of about nine feet in thickness.

Leaving this tunnel and going back to the shaft again, it was continued down until the depth of 125 feet was reached, when another tunnel was run to the north, to again find the vein. But this time it was found with a dip to the south, and still broken in character. The work on the shaft being again resumed, it was continued down 25 feet further, when the 150-foot level was reached and the main tunnel commenced and run, as already described. But in sinking the shaft this last 25 feet the vein was intersected and cut entirely through, and found to be still broken, although not so much so as at the tunnel 25 feet above. Mr. M. is confident that when they strike it again, in the proposed extension south, that it will be beyond the break and in solid coal. Thus it will be seen that this company expects now to reach and work three veins of coal with but small labor comparatively.

These deep workings at the present time are being prosecuted with vigor, and the company hope to have all completed so as to commence shipping coal in the spring.

This company, besides securing by long lease the lands which their coal discoveries have invested with so much interest, have recently bought a tract of 300 acres lying on the east side and up the Corralitas creek, opposite the present town, and known as the "Rich" farm. After reserving suitable sites for their own buildings and coal yards, they propose to lay out a large town. It is a beautiful location, with an unsurpassed climate. If the company should succeed in their plans this proposed town no doubt will become one of the finest in the county. There is also a coal vein indicated on this "Rich" tract, about a mile above Corralitas. I visited the spot a short time since, and found that a tunnel commencing in the bluff on the east side of the Corralitas creek has been run 150 feet directly into the hill. The vein as now worked is a black lustrous substance, looking at the dump like black clay, but in the vein, viewed by the miners' torches, it looks like solid coal. Wherever there is a breakage in the black mass, as well as where the pick has cleaved it, it has a polished surface. It has a sandstone wall on either side much harder than the substance of the vein. The miners informed me that they found occasional pieces of pure coal in the vein, but I did not see any of them. They are now running an incline to obtain the depth at which they think the solid coal exists.

Mr. Strader, the gentleman whom I have before mentioned as the discoverer and resident director of the coal mines, showed me coal which he recently discovered in a vein a half a mile or more below the present mines. This vein is shown running into the hill in a northerly direction, seven feet in thickness, and exposed by a land slide, which had broken from the side of the hill. About 100 lbs. had been mined and found to be good blacksmith coal; so good that the blacksmith in Corralitas is using it. What I saw seemed to be of good quality.

Your correspondent is not a coal expert, and does not assume any responsibility in regard to this whole coal matter, beyond giving the facts as he observed them; and yet from these observations he is constrained to believe that there is an abundance of coal here, and although much more may be required to be done to make it pay, yet pay it must ultimately. All honor to these men, who, notwithstanding every discouragement and continued opposition, have persevered for over two years in their purpose, until now success has not only promised to themselves large pecuniary reward, and justifies their superior capacity and fitness for their work, but has also opened up to the entire county such a source of wealth and prosperity as to entitle these men to be regarded as public benefactors.

Watsonville, Jan. 19th, 1877. C. N. W.

Cost of Smelting.

The Coso Mining News says: On the afternoon of the 1st inst., the Defiance furnace, after a suspension of several months, started up, and for 17 days has been running without any interruption. It had to close down, however, on Thursday evening last, on account of a non-supply of coal, the snow having blockaded the roads to the coal pits. It is not thought that this state of affairs will last long, and, in fact, Mr. Reddy assures us that he will start again within two weeks. As the Defiance has heretofore been a non-paying concern, for reasons not necessary now to state, we have taken the trouble to interview Mr. J. S. Gorman, Superintendent of the furnace, to ascertain the actual cost of smelting the Defiance ores. We found him very communicative, and he has given us a statement in detail of the expenses incurred for running the furnace for 17 days, and as the New Coso company is thought to be running very successfully, we give the figures for the cost of each. We presume, taking all things into consideration, it is nothing discreditable to the New Coso, and we give the figures for its benefit, hoping they may prove beneficial to the company. Although we did not obtain the figures from the Superintendent, we can assure our readers they are quite correct. Following is a tabulated statement of the expenses of running the New Coso furnace for one day.

New Coso Expenses for One Day.

One Foreman.....	\$ 10 00
Two Assistant Foremen.....	10 00
Two Engineers.....	10 00
One Machinist.....	6 00
One Blacksmith.....	5 50
One Helper.....	4 50
One Carpenter.....	5 50
Three Changers.....	15 00
Three Smelters.....	15 00
Three Helpers.....	12 00
Two Coal Passers.....	9 00
Five Laborers (ore men).....	20 00
One Cartman, Horse and Cart.....	6 50
One Night Watchman.....	5 00
Iron Ore, six tons per day, used at \$10.50 per ton.....	99 00
Lime Rock, 14 tons per day used.....	50 00
Charcoal, per day.....	396 00
Wood, six cords per day.....	66 00
Water, per day, 3,000 gallons.....	30 00
Sundries, Oil, etc., etc.....	5 00
Total expense per day.....	\$ 780 00
Total expense for 17 days.....	13,260 00

The furnace is of 50 tons capacity, and, when running well, smelts an average of 20 tons of ore per day.

Defiance Expenses for Seventeen Days' Run.

Coal, 14,800 bushels, at 32 cents.....	\$4,736 00
Labor.....	1,564 00
Wood, 34 cords at \$11.....	374 00
Iron ore, 30 tons, at \$16.50.....	495 00
Water, at \$22 per day.....	374 00
Sundries, at \$8 per day.....	85 00
Total.....	\$7,628 00

The furnace is of 30 tons capacity, and has smelted in the 17 days' run, 550 tons of ore, at an average cost per ton of \$12.05.

By these figures, which are very nearly correct, it will be seen that the Defiance has smelted its ores at an expense of \$12.05 per ton, whereas the New Coso company has smelted its ores at a cost of \$99 per ton. It is no disparagement to the New Coso, for it labors under difficulties of inexperience of boss smelters and managers not known to the Defiance company. It is to be regretted that the Defiance is compelled to shut down just at this time on account of weather elements, but the above statement is so satisfactory that creditors and all concerned will unite in lending their aid for the further prosecution of work. The company has now as much ore on the dumps as when it started, and the mine is placed in such shape that, when again started, both furnaces will be kept fully employed.

Dry Gold Separating Machine.

The Wheatland Free Press says: We visited the old Camp Far West mining ground last Tuesday, to witness the working of Carter & Irving's new method of separating gold. Mr. Irving, the inventor, is a practical millwright, and has spent eighteen years in bringing the machine to its present condition. The two great difficulties that present themselves are first, to run through enough dirt to make it pay, and second, to save the fine gold. Both, we believe, are accomplished in this machine. The dirt is carried by elevating rings to a drier, which consists essentially of three perforated cylinders, with the flanges on the inside, and revolving over a fire. When the material leaves the drier, it goes in three different grades into a pipe divided into three apartments. The lower apartment is for the finer dust, the middle for the next finest, and the coarsest at the top. A current of air is caused to pass through the pipe, which by means of valves can be regulated in any of the apartments at pleasure. Riffles are provided in the pipes, and the lower apartment, where the finer material passes, is provided with quicksilver. These pipes may extend to any desired length, and it would hardly be possible in a long distance, for the gold to escape the various traps set to catch it. When it is remembered how much ground there is in California where gold in paying quantities is known to exist, but where it cannot be practically mined for want of water, the importance of a machine that will separate gold without water will be appreciated. We think this new machine of Carter & Irving will do it in such a way as to make it pay, and will convert many of the old waste places of California into rich gold fields.

Rights of Stockholders.

The following is the full text of the bill before the Nevada Legislature, entitled "an act to protect the rights of owners of stock shares and other interests in the mineral and metal yielding mines of Nevada:"

SEC. 1. Any person who shall be the bona fide owner of stock shares representing the value of two per cent. of the capital stock of any company incorporated for the purpose of working upon and mining in any lode, ledge, deposit or bed of the precious metals, or useful minerals in this State; and any number of persons who shall be the bona fide owners of an aggregate number of mining shares amounting to two per cent. of said capital stock shall, by a duly accredited agent, upon a written order from the clerk of the county in which such lode, ledge, deposit or bed is located, be entitled to the privilege of fully examining all of the shafts, adits, borings, drifts, stopes, hoisting apparatus, and every and all properties and appurtenances belonging to such mining company; provided, such privilege for examination shall not be permitted except during one day during each calendar month.

SEC. 2. The county clerk in each of the counties of this State shall keep in his office a suitable book of registration, in which he shall enter the names of all persons who shall be entitled to the privileges granted by this act; and the county clerks of the several counties in this State are hereby authorized to administer an oath, or affirmation, to each and every applicant for said privilege; and for administering such oath, or affirmation, and for registering the name of the applicant, the clerk shall receive a fee of one dollar, to be paid by the applicant at the time of registration.

SEC. 3. Upon making application for the privilege of entering and examining any of the mines or mining properties mentioned in section one of this act, the applicant shall present to the county clerk certificates of stock-shares representing in value two per cent. of the capital stock of the company whose mine he desires to examine. Thereupon the applicant shall make oath, or affirmation, that he is a party in interest in the stock-shares of the mine and mining property which he or she desires to examine; that the stock certificates presented by him or her are actually his or her own property, or that such certificates of stock really belong to the parties which he or she is authorized to represent; that such stock certificates have not before been presented during the existing calendar month, and that they will not again be presented at any time during said calendar month.

SEC. 4. Immediately upon complying with the provisions of section three of this act, it shall be the duty of the county clerk to furnish the applicant with a written order for admission to the mine and mining properties which he or she may desire to examine.

SEC. 5. Any person who is a party in interest in any incorporated mining company in this State, and any mining superintendent, or mining foreman, or mining secretary, in this State, acting under and for such mining company, who shall fail or refuse to comply with any of the conditions mentioned in section one of this act, shall, for each and every such failure or refusal, be deemed guilty of a misdemeanor, and upon conviction in any court of competent jurisdiction, shall be fined in any sum not less than \$100, and not exceeding \$500, or by imprisonment in the county jail for a term not less than 30 days, and not exceeding six months, or by both such fine and imprisonment.

SEC. 6. This act shall take effect immediately after its approval by the Governor.

Mining in Russia.

The *Economiste Francaise* states that the mean average of production of iron in Russia is 320,000 tons. In 1874, the metallurgical establishments belonging to the State in the Ural mountains, in the district of Olonetz, in the east and the west of Poland, and in Southern Russia, produced 202,501 tons of cast-iron, 8,994 tons of unwrought iron, 1,151 tons of steel, 8,203 tons of war projectiles, 146 tons of steel for cannon, 241 tons of iron for cannon, 169 tons of armor plate, 46,695 sabers and bayonets, 5,735 muskets and locomotives weighing 177 tons. In the single district of Gorbolodatt, in the Ural mountains, from 35,000 to 40,000 tons of iron ore are extracted every year, and, since 1813, these mines have yielded 1,290,322 tons. The extraction is very easy, for many of the beds of ore are close to the surface, and the quality is very good. The manufacture of steel is also making rapid progress, and several of the State establishments employ the Bessemer system, among others the cannon foundry at Obouchoff, near St. Petersburg. The great central market for iron in Russia is Nijni-Novogorod, to which the Ural mines alone send down the rivers Bulaya, Kama, Volga, and Tchoussora, in barges, and, as the navigation is very dangerous, many of them are lost, especially on the Tchoussora. The iron sent to Nijni-Novogorod has to pass through three hands before it reaches the consumer, so that the price of it is very much enhanced. A great deal of the iron sold there is sent into the neighboring districts and to St. Petersburg, while at Riga and Odessa it has against it the competition of foreign iron and of that sent from the State establishments of Tombof, Riazan, Vladimir, and Kalouga.

USEFUL INFORMATION.

Glycerine and Its Uses.

This substance, says the *Polytechnic Review*, which has of late years attained a position of considerable technical importance, exists in the form of glycerides—in combination with the solid and liquid fatty acids, in most of the fats, to the extent of eight or nine per cent. From these combinations the glycerine may be separated by treating them with certain bases (such as potassa, soda, lime, or oxide of lead); or with acids (sulphuric acid), and certain metallic chlorides (chloride of zinc); or finally, by the action of superheated water. Glycerine is likewise one of the products of the alcoholic fermentation of the several fermentable varieties of sugar, forming, according to the researches of Pasteur, about three per cent. of the weight of the sugar.

We append in what follows a list of the more important uses of this substance. It is employed to keep modeling clay in properly moist condition. It is excellently adapted for the preservation of articles of food, and especially of fruits which require to be kept in a moist condition. It is used in the manufacture of liquors, essences, and the like, as a sweetener; and its sweetening and preservative properties have caused it to be largely employed as an addition to wines and beer. As a lubricant, especially for fine machine work, such as the working parts of clocks, watches, chronometers, sewing machines, glycerine has been found well adapted, in virtue of its non-habit to decompose or freeze, and its indifference to metals. It has been found to make an excellent copying ink, when added in small quantity to such writing fluids; letters written with ink to which glycerine has been added do not require the wetting of the copying paper, but may be copied dry even for some time after writing. In virtue of its property of keeping the skin soft and moist, glycerine is employed pure, and in a number of preparations (glycerine soap, pomatum, etc.), and medicinal mixtures, as a cosmetic, in cases of burns, catarrhal affections, etc.; and from the same property of this substance—its avidity for moisture—it has found application in several industries, such as paper making, weaving, dressing of leather, etc., where it is found desirable to give to fabrics great softness and flexibility, and do away with the subsequent tendency of such articles (as leather belts and the like) to dry and crack. It is extensively used as an ingredient of printer's rollers.

As a solvent, glycerine occupies an important place in medicine and the arts; it is particularly valuable as a solvent for gum arabic, as also in paste. Glue, by continued digestion, is soluble in glycerine, gelatinizing on cooling. Glycerine dissolves aniline violet, alizarin, and alcoholic madder. A solution of aniline colors in glycerine is often used for stamping with rubber hand stamps. Glycerine is employed to extract the perfume from flowers, and the aromatic principle of red peppers. Sulphate of quinine dissolves in ten parts of glycerine when hot, but when cold, separates in clots, which, when triturated with the supernatant liquid, gives it the consistency of a cerate, very useful for frictions and embrocations. Fifty parts of warm glycerine will hold in solution, when cold, one part of salicylic acid. Three hundred parts of water may be added without causing precipitation. A mixture of carboic acid and glycerine has been suggested as a preservative agent for green skins, as a substitute for the salting generally practiced. The carboic acid increases the preservative effect of the glycerine, while the action of the latter keeps the skins perfectly soft and fresh, just as they were directly after slaughtering.

One of the most important applications of glycerine is its use in wet gas-meters. Water possesses the disadvantages of freezing in winter and of evaporating in the warm seasons, while a mixture of equal parts of glycerine and water is free from both of these evils.

A few drops of glycerine in mercurial gauges, etc., have been found to prevent the formation of the objectionable slimy film that shortly makes its appearance on the surface of the quicksilver column. It has been recommended for keeping guns and pistols clean and free from rust. It is found well adapted for the preservation of anatomical preparations, and for the saturation of barrels intended to contain petroleum, etc.

Lastly, it is employed in great quantities for the production of that most powerful and valuable of all known explosives, nitro-glycerine, made by a treatment of glycerine with a mixture of sulphuric and nitric acids. We have no figures at hand from which to estimate the total magnitude of the glycerine industry of the world, but its extent may be imagined from the statement that in the United States alone there is annually produced not less than 2,000,000 lbs.

To Obtain the True Meridian.

In all of recent works on surveying, it will be found that Alioth, the first star in the handle of the Dipper, is designated as being directly opposite the pole from Polaris, the north star. There was a time when such was the case, but now it is far from being correct.

The first published account of this method which we have been able to find is in a revised edition of Abel Flint's work on surveying, published in 1833, which states that this method was communicated to the compiler, with per-

mission to publish, by Moses Warren, of Lyme, Conn. It appears that this mode of reckoning had been in use among surveyors for some time previously; but we have not been able to find by whom or when it originated.

In 1800 Alioth was opposite Polaris; but a retrograde movement of the latter, of about 20 seconds a year, has caused Alioth to be, at the present time, 25 minutes ahead, and brings Mizar, the second star in the handle, within five minutes of being opposite; so that, in 15 years more, Mizar will be exactly opposite. Polaris is on the meridian 25 minutes after Alioth has passed the perpendicular, and five minutes before Mizar reaches it.—C., in *Sci. Am.*

BRASS COATING FOR IRON WARES.—The coating of iron goods with brass, according to Herr Hess, has not attracted the attention it deserves. It is admirably adapted, according to this author, for a great variety of articles of iron, partly to preserve them from rusting and partly to beautify them and enhance their value, and among the objects for which it will be found suitable may be enumerated: ordinary keys, door-bells, furniture springs, cast door-plates and signs, statuettes, certain kinds of hollow ware (if tinned inside and brassed outside they present a fine appearance), smooth turned door knobs, nails, wire, etc., used by cabinet makers, etc. The process is as follows: The first step is to thoroughly cleanse the articles, either by means of emery, or by laying them over night in a weak bath of sulphuric acid. They are then to be washed off with water, a weak soda solution, and then immersed as the cathode of a bath consisting of 2½ parts of sulphate of copper, 20 parts of sulphate of zinc, and 45 parts cyanide of potassium, in 300 parts of water. The anode should be two plates of zinc and copper of equal size. The color of the resulting brass coating may be modified by varying the depth of immersion of one or other of the plates. The galvanic current should be a strong one, and the liberation of hydrogen bubbles on the object to be brassed should be plentiful. It is important, however, to note that the objects should be first coppered to insure a strong attachment of the brass coating.—*Metallarbeiter.*

TESTING POISONOUS WAFERS.—Poisonous red wafers, which, more than 50 years ago, were detected as very injurious, seem still (according to *Stunner's Ingenieur*) to be in extensive use. A simple method of recognizing the poisonous character of such wafers has been suggested by M. Feldman, of Detmold. You stick a needle into a wafer, saturate the latter in a few drops of petroleum and light it. When the burning wafer has become a glowing mass, blow weakly on it. While you do so, the metallic constituent drops down, and may be caught on a porcelain plate or a piece of white paper. Even with the naked eye one may recognize the lead granules, and the better if one presses them first with some hard and smooth substance—e. g., a knife handle.—*English Mechanic.*

ANILINE POISONING.—We find the following in an Eastern exchange: "A man wore a new felt hat for one day, and though it did not press on his head he had severe headache. An eruption appeared, attended with swelling of his forehead, proceeding in some parts to suppuration. The eyes also became inflamed and almost closed, and the swelling extended more or less over the whole face. A chemist found, on examination, that the brown leather lining was colored with an aniline dye containing poison." [The foregoing is similar in effect to the poison which one of our correspondents lately reported with blue shirting. Many colors are made with the same group of substances known as aniline dyes.—EDS. PRESS.]

GOOD HEALTH.

Medical Progress.

It is true, says the *Manufacturer*, that medical practice is still, in many respects, defective, empirical, tentative and even sometimes mere guess-work; hence the carefulness of those who know the deficiencies of the healing arts, while boldness in prescribing belongs especially to quacks, who act after the maxim, "kill or cure," and mostly 'kill; but, luckily for the quacks, the surviving relations of a diseased patient usually think that he would have died, notwithstanding the medicines he took, while, in fact, the patient who did not die, recovered, notwithstanding the drugs he swallowed.

In the meantime, with all the deficiencies of the medical art, and the little benefit enjoyed often by single individuals, the good done by the clearer insight of the causes of diseases, the study of preventatives and of the correct principles of hygiene has been an immense blessing to mankind in general.

In order to realize this fully, we have only to look at the death lists of large European cities two centuries ago, and we find that a large portion of the then mortal diseases have been deprived of their dangerous tendency, and several other diseases have become extinct. Many people then died of fever and ague. Cromwell died of it. At present it is no longer mortal in the temperate zone, and the reason is that improved drainage and cleanliness on the part of the people in general have caused the disappearance of the moist, foggy and unhealthy atmos-

phere which surrounded then the dwellings in every densely populated district. Dysentery, or bloody flux, formerly caused many deaths; now it is seldom fatal. Small-pox was the most terrible of all diseases, carrying off victims by the hundreds, and scarring or blinding others by the thousand. Spotted fever, scurvy and the plague prevailed every year somewhere, but now they all are diseases of the past, and this by reason of the more correct knowledge of their nature and the means applied, resulting either in a total prevention, or at least in giving the disease a more mild form and favorable result. Even cholera, which first appeared in Europe 45 years ago, has, by a better knowledge of its nature, lost some of its former infallible malignity. It is the same with scarlatina; and we enter upon the threshold of so much knowledge respecting the nature of phthisis, that we may justly hope to see this scourge of families become more and more rare, and this by preventative measures, to be applied when there is a tendency in that direction.

Preventative medicine is slowly attaining such a degree of perfection, that the time is not very distant when the occurrence of an epidemic will be a reproach to city governments, while the chief functions of the foremost physicians will be the preservation of the public health. This assuredly will be a most noble calling, and the present boards of health, established in our large cities, is a move in the right direction, and has already been a benefit to the inhabitants which they cannot value at too high a price.

Eucalyptus Tea.

The editor of the *San Diego World* gives the following personal experience: Some months ago the writer read in an English paper of a discovery by some physicians in Europe of the value of the eucalyptus in early stages of cold and fever. Some weeks ago, being taken with a severe cold, we made a decoction of eucalyptus leaves and drank it on retiring to bed. The result was that it brought on a gentle perspiration and sleep, and in the morning all symptoms of the cold had disappeared. A fortnight ago a friend of ours was seized with cold and fever. He had aching pains all over his body and to every appearance bade fair to be confined to his room. We thought of the eucalyptus and told him of our experience. He went home and had a strong decoction made and drank freely on going to bed. It worked like a charm, for he was in perfect health the next morning, only a little weak from profuse perspiration. His wife was suffering from cold at the time and tried the remedy and found it a perfect and immediate cure. One instance more in our own case. Last night, just before retiring to bed, we were seized with a violent chill, accompanied with pains in the back and legs. This was followed by a little fever. These symptoms had presaged a very serious illness a year or two ago, and we thought ominously on the subject. We sent out to the street, had some leaves plucked and our favorite tea was made at once. We drank about a pint and soon fell asleep and to the credit of eucalyptus we say we are as well to-day as ever we were in our life. Our opinion is that the tea is perfectly harmless to drink even a large quantity of. For a medicine tree we can recommend everybody to grow eucalyptus.

THE POISONOUS PRINCIPLE OF SPOILED CORN.—Professor C. Lombroso describes two poisonous principles derived from spoiled maize: an oil soluble in alcohol, and an alkaloid. From these may be derived a body closely resembling strychnia, possessing all of the chemical and most of the physiological reactions of the latter alkaloid. In frogs, not only tetanic symptoms, but also those of paresis and narcosis, were induced by administration of the oil. In chickens, after prolonged administration of the oil, only paresis and convulsive movements of the head, with inclination to retrograde movements, were induced. The administration to chickens of the alkaloid, on the other hand, induces death in a few minutes, with previous paralysis of the limbs and chronic convulsions. Administered to locusts, fish, mice, etc., the alkaloid gives rise to symptoms similar to those of strychnia poisoning. Professor L. concludes, therefore, that two distinct poisons are present in spoiled maize.

TOO MANY SWALLOWS.—Eating, like all other things, can be carried to excess. The requisite amount swallowed goes to build up the person; all other food eaten is superabundant, and goes to swell out the stomach. It is fallacious reasoning to say that a fine physique can be produced by gormandizing. The physique of the Scotch Highlanders is immeasurably better than that of the Germans, and yet the Highlanders are exceedingly abstemious. Heavy eaters are apt to be exceedingly dull people. They clog the brain in catering to the wants of the stomach. They are like a boa constructor; they eat until they can hardly see or move, and are compelled to loll about after a dinner, closely resembling a pig. It is impossible for such people to be possessed of acute reasoning powers.

TARTARIC ACID IN COOKERY.—This acid is put up under the false name of fruitina, and is largely used to make tarts, pies, etc. It is not a rank poison, but cannot be used very extensively without harm, and is no substitute for fruit.

NEW ADVERTISEMENTS.

Artificial Limbs, Menzo Spring, S. F.; Delinquent Assessment Notice—Great Blue Gravel Range Company.

A BONANZA CASE.—Hugh J. O'Reilly and wife have filed a complaint in the Nineteenth District Court against Flood & O'Brien, which avers that plaintiff was the owner of 484 feet of the White & Murphy claim on the Comstock lode; that on the 25th of January, 1875, he sold this interest to the defendants for 100 shares of Consolidated Virginia stock, which has since been subdivided into 500 shares; that plaintiff made a conveyance of his interest to the Consolidated Virginia company and received a bill of sale for 100 shares of that stock; that by agreement the stock was left in the hands of the defendants subject to call, the dividends to be paid plaintiff; that on the 29th of January, 1875, plaintiff assigned the 100 shares to his wife; that defendants collected dividends on the stock and paid over to plaintiff only four of them; that in March, 1875, the defendants repudiated the contract and refused to pay. Therefore, judgment is demanded for a delivery of the stock or \$60,000, value thereof, and \$17,000 dividends. As a further and separate cause of action, O'Reilly alleges that at the time of the sale, on the 25th of January, 1875, the defendant agreed with him that he should have the option of taking \$150,000 in gold coin in lieu of his 100 shares of stock if he should desire to do so six months after January 25th, 1875. He then goes on to allege in the other complaint the acceptance of the contract on plaintiff's part, the leaving of the stock in defendants' hands, and their repudiation of the contract. He therefore asks judgment for the \$150,000, and \$2,000 dividends improperly retained under the second agreement.

JUDGE WILLIAMS, of the 19th District Court, has vacated the order appointing a receiver in the case of the Lady Bryan mining company, and has decided that the court has no right to order a new election. This disposes of the entire matter in favor of the present management.

The "Tailings" Case.

The judgment rendered by the Sacramento District Court, on the 26th ult, in the suit of Atkinson against the Sacramento and Amador Canal Company, for damages done to the plaintiff's farming ground by the deposition upon it of sand and gravel washed from the defendant's hydraulic mine, is one of importance to the mining interests. We give in another column the decision in the case, as well as the Judge's instruction to the jury, which it is important for all interested in this matter to read carefully. This was the first case of a series of the same kind, and has been considered a test case. The decision is apparently more favorable to the farmers than the miners, but, on examination, it will be seen that if the Judge's charge be held as correct by the Supreme Court, the burden of proof will rest on the farmers, and in the case of distant mines this gives a great advantage to the miners.

We gave in a late issue the substance of the whole controversy between the miners and the farmers, in a general way. This particular case is somewhat exceptional in its nature, and that in a very important point. The land injured was not situated like that along the banks of the Feather, Sacramento and other rivers, 40 or 50 miles below the mines, but was close to the mines. The debris was deposited almost directly on the farming land. It was shown in evidence that the flume boxes of the Pet mining company actually extended across the line of Atkinson's land and emptied the rock, sand and dirt on his land, while the water from the sluices carried the lighter parts and spread them over the bottom of his ground on Arkansas creek. The plaintiff was able, of course, to trace directly the tailings to this claim, and it is a significant fact that, although evidence was offered to prove that other companies contributed to the damage, this evidence was ruled out. It devolved on the plaintiff to prove that the company had done the damage.

With the question of title the jury was instructed that it had nothing to do. It was simply to decide whether the land was damaged or not, by whom, and how much it was damaged. Of course it was damaged by tailings being dumped directly on it, the same as if any miner dumped his waste dirt in the garden of some resident near by. But we are sure that in such a case, even among miners damages would usually be paid without recourse to the courts. The jury visited the ground, saw the state of the case and decided accordingly. The plaintiff proved that the "slickens" were deposited directly on his land from the defendant's mine, and were caused to be so deposited by the direct action of the defendant. This direct testimony was what decided the suit as it was decided.

Judge Sexton, however, in the case, charged the jury among other things as follows: "If the defendant discharged, in the usual and ordinary working of mines, water, tailings, earth and other matter upon the banks of Arkansas creek at places remote from plaintiff's land, and such matter, in the course of nature and from the effect of natural floods flowed in and down said creek and was deposited, portions of it, upon plaintiff's land, the defendant would not be liable to damages; but if the deposit of sand and gravel and sediment was deposited in such close proximity to the land that it must of necessity pass upon the land of plaintiff, the defendant would be liable for all damage done by defendants."

Under this ruling, if it is confirmed by the Supreme Court, the miners of Dutch Flat, Moore's Flat, Bloomfield, San Juan ridge, and in fact almost everywhere else where the districts are high up the mountains, will be safe from the farmers. All the great hydraulic districts in Nevada, Placer, Sierra, Butte, El Dorado and Yolo counties, where hundreds of mines discharge their tailings into the Bear, Feather, Yuba, or American rivers, are not affected by the decision.

The companies may float their tailings into a canyon or gulch, where they will lie until winter's floods sweep them over the valley, in which case no recourse can be had under this ruling.

During the progress of the trial the defendants wished to offer in evidence the following allegations. They foreshadow in part the issues upon which the case rests, and will be fought on appeal.

First.—That the defendant is a ditch company engaged in mining, and that it has a grant from the Government of the United States to construct its ditches—which grant antedates any title or right that the plaintiff has to this land, and that under that grant the defendant has the right to run the water upon this land.

Second.—That in accordance with the customs, rules and decisions of the courts, defendant as a ditch owner had the right to discharge this water charged with sediment and tailings into Arkansas creek, which right antedated any right plaintiff had to the land, and that the plaintiff's land was public land of the United States at the time the grant was made, and that he had no right, at law or equity, to any part of it.

Third.—That there are over 500,000 acres of mineral land in California, gravel deposits, that can only be worked by hydraulic mining, nineteen-twentieths of which have not yet been

mined, and that the one-twentieth has produced over \$900,000,000 since they have been worked, and that these mines have always been worked in the same manner in which defendant worked its mine, and cannot be worked in any other way.

Fourth.—That the value of the agricultural land in California which can be affected by mining does not exceed \$200,000.

Fifth.—That unless the mines in California can be worked in the manner as defendant worked its mine, they cannot be worked at all, and will be of no value whatever.

Sixth.—That the defendant had mined in the same manner as that in which mining has been conducted on like land since the first settlement of the country.

Seventh.—That defendant has not conducted its business negligently, carelessly or in an improper manner.

Eighth.—Before and since the admission of the State it has been and is the custom of miners to throw the tailings from the mines into the natural outlets and water courses leading from such mines.

The propositions given above all relate to very material facts, and, doubtless, the superior court, in the new trial which will come off, will admit them, or some of them. Even if the tailings on some of the ranches in Sutter and Yuba counties can be traced directly to some particular mine, it appears probable that to recover damages the owner of the farm must prove that his title was obtained before the passage of the federal statute of 1866, recognizing the titles of mining claims and ditch claims, and giving their owners priority of right, so far as there might be any conflict, over titles to agricultural lands subsequently purchased from the United States.

The expenses of this suit were probably not less than \$4,000, and if the decision is confirmed by the Supreme Court, immense sums must be spent in costs and attorney's fees during the next few years, for as long as there is any gold the miners will continue to work their claims and count the "damages" as so much additional expense. There are other suits now pending, one of which is that of Keyes, of Sutter county, against the miners in Nevada and Placer counties, but that will be in favor of the miners if Judge Sexton's rulings hold good. In any instance the cases will be taken to the higher courts, and it is probable that the associations of the farmers and miners will pay the expenses of the respective contestants in these test suits. The question has thus far been only opened, but enough has been developed to show the points on which the fight is to be made. As far as it goes it seems more favorable to the mining interests than the farming, as the burden of proof rests on the agriculturists, and the ruling referred to above practically puts it out of the reach of the farmer to show exactly who damaged his land when the mines are at a distance from it.

BULLION SHIPMENTS.—Since our last issue shipments from the prominent mines have been as follows: Leopard, Jan. 18th, \$5,103.76; Chollar, 24th, \$7,061.74; Northern Belle, 21st, \$16,381.66; California, 25th, 21 bars, valued at \$86,736.24—total to date, \$574,601.39; Con. Virginia, 25th, 11 bars, valued at \$39,475.13—total to date, \$314,603.67; Comanche, 23d, \$4,691.94; Northern Belle, 23d, \$10,466.87; California, 27th, \$146,822.85—total to date, \$721,423.93; Con. Virginia, 27th, \$41,607.49—total to date, \$356,211.26; Tybo Con., 25th, \$11,959.80; Modoc, 25th, \$5,180—total to date, \$98,177; Chollar, 27th, \$7,220; Modoc, 27th, shipped 230 bars, value \$5,680; Tybo Con., 25th, \$5,870.71—total to date, \$39,961.27; Modoc, 27th, \$5,680—total to date, \$103,860; Leopard, 28th, \$5,900; Northern Belle, 25th, \$9,898.93; Modoc, 29th, \$10,680—total for January, \$114,540; California, 30th, \$173,417.45—total to date, \$894,841.38; Con. Virginia, 30th, \$55,146.29—total to date, \$411,357.41; Northern Belle, 28th, \$16,000.66.

PATENTS IN 1876.—The following is a summary of the forthcoming report of the Commissioner of the Patent Office for 1876:

	1875.	1876.
No. of applications for patents.....	21,638	21,425
No. of patents issued.....	14,837	15,695
No. of patents allowed but not issued for want of final fee.....	3,518	3,353
No. of caveats.....	8,094	2,697
No. of trade marks registered.....	1,188	1,081
No. of labels registered.....	313	3,902
Amount of cash receipts.....	\$871,000	\$874,000

THE Post's London special says: Colonel Gordon, the explorer, who returned from his expedition into the interior of Africa, under the auspices of the Khedive, and arrived in England a few days ago, has already received an urgent summons from the Khedive to return to Egypt. He has presented the Royal Geographical Society with valuable original maps, which he brought back from equatorial Africa, and has promised to contribute a paper of great interest.

THE aggregate deposits in the local savings banks on January 1st, 1876, were \$56,260,964, and on January 1st, 1877, \$59,627,191. The large line of deposits, as above shown, strongly attests the interest of the people of San Francisco in the stability and solvency of these banks.

A bill appropriating \$10,000 for a road from Phoenix to Globe mining district has been passed by the Arizona legislature over the Governor's veto.

Artificial Ice Manufacture.

Machinery for the production of artificial ice has been greatly improved of late, and numerous inventors have turned their attention in that direction. The subject of artificial ice manufacture, however, is one little understood by the general public, and the following description of an improved method just patented through the MINING AND SCIENTIFIC PRESS Agency, by Robert H. Lucas, of this city, will be found of interest.

This invention does not relate to any particularly novel step or new discovery in the chemical process of refrigeration by which artificial ice is made, but rather to the mechanical construction and arrangement of the apparatus employed. The object which the inventor attains is the production of ice in the ice molds or forms of an ice machine and the automatic removal of the blocks, cakes, bars or sheets of ice from said forms or molds, without manual labor, thus reducing the cost of its production to a minimum point. To accomplish this he necessarily remodels the ice machine and provides certain novel mechanical improvements.

An ordinary tank is taken, inside of which the molds or forms are placed at proper distances apart in the usual way. The tank is supported on legs so as to raise it a short distance above the floor for the purpose hereinafter explained. The tank is provided with two bottoms, placed a short distance apart, so as to provide a space between them, and the forms or molds, which are simply tubes of any desired shape, pass down through both of these bottoms, so that their lower ends terminate below the lowest bottom. To one side of the lower end of each tube or form is hinged a door, which may be kept closed against the lower end of the tube by a spring or weight, as most convenient.

Each of the tubes is surrounded with an outer case, which extends from near the upper end of the tube down to the lower end, thus forming a jacket around each tube. A hole just above the upper bottom connects the interior of the jacket space with the interior of the tanks. A pipe conveys the refrigerant gas through the tank and it is coiled around between the molds so as to subject every part of the interior of the tank to the refrigerating action.

Over each row or series of molds is led a water pipe, from which a branch pipe leads down into and terminates in the upper open end of each mold. This main pipe is connected with a pump or other water supply, and a rose or sprinkler is attached to the lower end of each pendent tube or branch pipe inside of the molds, so that when the water is turned on it will be sprayed through the rose, inside of and against the sides of the molds.

The tank is filled, or partially filled, with a saline solution or other non-congealable liquid, so that it will cover the refrigerant pipes and rise in the jackets around the tubes as high as the solution stands in the tank. Now, when this refrigerant gas is allowed to circulate through the pipes, and the spray of water is turned into the molds, the water will be frozen on the sides of the molds until each mold has been filled by gradual accretions.

An air pipe is coiled back and forth in the upper part of the tank so as to pass between each two series of molds. A short branch pipe connects this pipe with the jacket which surrounds each mold. The air pipe is connected with an air pump so that when the molds have been filled with ice, as above specified, air can be forced through the pipes into the surrounding jackets, and which will drive out the saline solution which is contained in them through the openings in the tank, thus interposing an air jacket between the saline solution and the ice.

Another pipe passes along under the tank and conveys hot water against the lower ends of the jackets or tubes below the hole in which a portion of the saline solution constantly remains, so that by heating this portion of liquid the heat is conveyed to the inner sides of the molds and doors and thus dislodges the blocks or cakes of ice, which will by their own gravity drop out of the tubes, falling upon the floor beneath.

Their weight will be sufficient to force the spring doors open and inclines or deflectors can be applied underneath the tank to direct and convey the blocks or cakes of ice to a point away from under the tanks. To facilitate the automatic removal of the blocks of ice the inventor prefers making the molds or tubes tapering or gradually wider towards their lower end, so that they will, when loosened by the heat, drop freely from the forms. Short exhaust pipes are used, through which the air in the jackets can be exhausted and thus allow the water to resume its level in the jackets.

It will be seen from the foregoing that this inventor produces the ice and removes it from the molds in which it is manufactured without manual labor in handling the blocks. One person can attend to the entire machine, and his attention will only be required as engineer, to start and stop the pumps and the cocks, which admit and exhaust the gas, air and water as each is respectively required.

WILLIAM J. LAWRIE is no longer agent for the publishers of this paper in this State.

Comstock Papers.—No. 15.

Pioneer Mills and Millmen.

Postponing, for the present, further reminiscences of the first claim locators on the Comstock lode, and their immediate successors, who together gave their names to most of the mines along it, we proceed to remark briefly upon the first efforts made in the way of developing these mines and providing reduction works for the proper treatment of their ores. As already stated, the earliest attempts at working the Comstock ores were made in the spring of '59 at Gold Hill, the means employed consisting of the common Mexican arastra, some half-dozen of which were in use there before the rich ore deposit at Virginia City was discovered. During the following summer and autumn the number of arastras here employed was largely increased, several having been started near the site of the new discovery, and also down on Carson river, these last being driven by water. In the spring of 1860 the Meldonado brothers, owners of the Mexican, or, as it was it was then called, the Spanish ground, erected extensive yards for working their ores by the patio process, there having, as yet, been no mills or other reduction works put up here for the treatment of the ores. Almarin B. Paul and the introduction of the Washoe Pans.

In the month of March, 1860, Almarin B. Paul, an experienced quartz miner, and skillful metallurgist, of Nevada county, California, made a visit to the newly found silver mines of Washoe, and after carefully examining the character of the ores, became satisfied that amalgamation could be thoroughly and economically effected through the use of the iron pans already employed in the gold mines of California. This idea was rejected as absurd by the old school of metallurgists, all of whom contended for the use of the German barrel or the Mexican patio process, some even insisting that the ores here could be satisfactorily treated only by smelting.

So thoroughly, however, was Paul impressed with the adaptability of the pan process for this purpose, that he instituted a series of careful trials directed to test the matter, the results of which fully confirmed his previous opinion. Satisfied that he was right, he determined that the mill which he had already concluded to put up in Washoe should be furnished with this and no other amalgamating apparatus. Having completed an organization styled the Washoe gold and silver mining company, No. 1, of which he was himself the moving spirit and almost sole director, Paul commenced on the 24th day of May, 1860, work on his new mill, which was located at a rugged pass on Gold canyon, known as the Devil's Gate, this site having been chosen because of its convenience to water.

The First Two Mills and a Close Race for Precedence.

On the 7th day of June, Paul gave his order to Howland, Angell & King, of the Miners' Foundry, San Francisco, for the iron work of this mill, which was driven by steam and carried 24 stamps. This machinery, with all needed supplies, was shipped over the mountains during the summer at an average expense of about \$400 per ton, this being before any wagon roads had yet been constructed over the Sierra. As there was but a single saw mill then running in the country, the lumber required for this mill cost at the rate of about \$300 per M, labor and material of every kind being proportionately high. Notwithstanding these and other obstacles, the projector and manager of this new enterprise pushed it ahead with such activity and vigor that he had the pioneer mill of Utah Territory advanced so near to completion that steam was let on and machinery started up on the 11th day of August, 1860.

It was by a single point, however, that Paul gained this distinction for his mill, that of Coover & Harris, situated at Gold Hill, two miles above, having gotten up steam and set its stamps in motion only an hour or two later on the same day, as appears by the certificate of W. H. Howland to that effect, he having acted as engineer for both of these establishments on that occasion. As this was only an eight-stamp mill, the labor and cost of its erection were proportionately less, though the iron work, turned out at the same foundry, was not ordered until two weeks later than in the case of Paul's mill, which latter cost about \$50,000.

Their Successful Career.

The two mills, though rude and unpretentious structures, compared with some of those soon after put up, had, nevertheless, a long and successful career, having made large earnings for the owners, while they served the mining public acceptably and well. Paul's first run was on Gold Hill ores, Alpheus Staples having given him a contract to work 4,000 tons, at \$30 per ton, an arrangement that resulted to the mutual satisfaction and advantage of both parties. He had at the first endeavored to get a contract from the Ophir and the Gould & Curry companies, but they declined to furnish him with ore, being timid about his proposed method of amalgamation. Before his mill had been running a week, however, he had engaged to work ore to the amount of nearly half a million dol-

lars, and so numerous were the applications thereafter, that he commenced, within three months, building near the town of Gold Hill another mill, which was to carry 64 stamps and cost \$150,000.

The First Clean-Up

Made by him, amounting to several thousand dollars, was carried in iron kettles to Rhulung's assay office in Virginia City, where its appearance after being retorted created quite a stir, this being the first bullion produced in the country. It had, moreover, been demonstrated that pan amalgamation, since known as the Washoe process, would answer in the treatment of these Comstock ores, a fact that gave a new impetus to mining and imparted additional value to "feet." It is worthy of note that the first at-

many of them to serve the purpose at that.

The Coover Mill

Also ran at first for the most part on Gold Hill ores, the proprietors, Charles S. Coover and Dr. E. B. Harris, having contracted with Pluto and Bowers to work their ore at \$25 per ton. The building occupied by this mill was a mere shed, composed of rough lumber, and no one in passing by would have supposed it of much account. But the machinery was good, and it was run by a man who thoroughly understood and carefully attended to his business. Pass it at what hour you might and this mill was in motion, and so it continued for several years, giving the best of satisfaction to all who patronized it, while it enriched the owners. It afterwards passed into the hands of C. C. Stephen-

THE WENGLER ORE CLASSIFIER.

tempt at working the ores of the first silver mine ever found and opened in the country should have been attended with the inauguration of a process so distinguished for its efficiency and so essentially its own.

A Retort of Preposterous Dimensions.

Paul, entertaining a pretty high notion as to the richness of these Washoe ores, had taken over for use in his mill a retort of about 300 pounds capacity. This implement having been thrown out and for some days exposed to the public gaze, excited the jeers of passers-by, who tauntingly inquired of the over-sanguine mill builder if he expected to ever fill the thing with amalgam. The first clean-up having more than filled this retort, put an end to these jocular remarks upon its extravagant dimensions. The retorts now in use at the larger Washoe mills hold several tons each, and it takes a good

son, who also made money with it, but standing close to the wagon track, and proving to be quite in the main street of Gold Hill when it came to be widened and straightened, this venerable and useful structure was torn down and the machinery removed to eastern Nevada, where it was again set up and has since been pounding away as industriously as ever on the silver bearing ores of that region.

The ship *Orient*, now loading for New York, will carry a consignment of 4,000 bundles shingles and 50,000 feet redwood boards. This is a new outlet for our surplus lumber and its products.

J. B. Ford & Co., the well-known publishers, have gone into bankruptcy for the second time, having failed to carry out the terms of their first compromise with their creditors.

Mechanical Ore Concentration and Separation—No. 20.

[Written for the Press by FRANCIS M. F. CAZIN, M. E., Santa Fe, New Mexico.]

Classification by screens will in practice act with success whenever the capacity of the screen is equal to the volume of ore fed into such screen. The capacity is not determined by the size of the screen alone, but by its rate of motion also, and therefore it is wise to provide screens and their driving shafts with cone pulleys, permitting the acceleration of their motion under greater requirement. Although screens made out of proper material, such as sheet copper and sheet steel, last longer than commonly supposed—the water acting as a lubricator and protector from rigorous friction with the ore—they are costly in make and maintenance. For coarser sizes they can not be successfully replaced by any known apparatus, but for the sizes from stamp batteries (one and one-half millimeters and less), classifiers of another system and based on other principles may be employed with good success. As an instance of this class of classifiers, we quote an apparatus known as

The Wengler Classifier.

This apparatus, although lately patented in the United States, has hardly any feature which would be maintained as new and as not applied in practice and described in print a long time previous to the patentee's application, it being the old Spitzlutt with an arrangement of water supply and discharge more or less modified in unessential parts from what was customary.

The Wengler classifier consists of five reversed pyramidal-shaped vessels, increasing in size, which vessels, when full, are in communication with each other; they are shown in the engravings from I to V. From the bottom of each vessel there extends a tube, as shown at a, b, c, d and e, and each tube is connected with a tubular foot piece, as shown at f, g, h, i and k. From a trough, G, situated some distance above the apparatus, a series of five tubes, l, m, n, o and p, extend down and connect each with one of the foot pieces. The trough, G, serves as a clear water conduit to supply water to the tubes, f, g, h, i and k. Attached to each of the tubes last mentioned are small sluices or gates, q and r, intermediate between which is the lower end, a, b, c, d or e, of the vessel which opens into the tube. The sluices serve to regulate the influx of water, and the efflux of the corn or kernels of ore.

The trough, H, serves as a conduit for the stamped material as it comes from the stampers. At the other end of the apparatus is another trough, J, which carries off the slimes.

The water in the trough G, is, as before stated above, the level of that in the main portion of the apparatus, and it therefore has a more powerful head; consequently, if the sluices be so adjusted that the efflux opening at r be smaller than the influx opening at p, then a part of the pure water which would otherwise flow out at r, will reach up and against the downward current on, for instance, the tube a. It will therefore be seen that it is possible for such grains, only, whose weight is greater than the resistance of the upward reacting stream, to flow out at r, the other and finer ores, together with the slime, flowing over into section II, where the same operation is repeated, only on a finer scale, and so on to the last section or vessel, which receives all the slimes and the ore of ultimate fineness. Here the operation is again gone through with, and, by a simple adjustment of the sluices of this last section, all the slime is made to pass over into the trough, J.

The assorting of the different sizes can be accurately regulated, inasmuch as the slightest movement of the sluices has a remarkable influence upon the classification, and according as the reacting stream is stronger or weaker, the grain classified thereby from the mass of stamped ore will be correspondingly coarser or finer.

But in this influence exercised on the action by the movable sluices or slides consists the weak point of the system in practice. The apparatus is not self-acting automatic as screens are, but requires skilled regulation, not only when put up, but constantly, and the least change or interference with the sluices, slides or valves destroys the correct action totally. Where skilled labor is scarce and therefore costly, the more reliable system of classifying by screens is preferable.

Out of 1,357 cases of small-pox reported in this city since May 19th, 1875, there were 395 deaths. The number of deaths from diphtheria since July 1st, 1875, was 454, of which 110 occurred in December. In the four weeks ending January 26th there were 116 deaths from this disease.

The importation of horned cattle and sheep from Germany, England, Russia, Austria, and Turkey into Belgium, is prohibited by royal decree. The British authorities have issued further stringent orders against the importation into Great Britain, from Germany and Belgium, of cattle, hay, hides, horns, fat, hoofs and fresh meat.

The first engine built in San Luis Obispo county has just been turned out at Philbrick & Barneberg's shop. It is of 20 horse-power,

California State Geological Society.

Opening Address of the President, Henry G. Hanks.

The society which we meet this evening to organize has two distinct objects in view:

First—The collection of material for a State museum of Pacific coast rocks, fossils, ores and all inorganic substances having a bearing on practical geology. We hope by our individual exertions and the assistance of those interested in mining and manufacturing industries, to form a collection which will be both valuable and instructive. We shall, as soon as possible, throw it open to the inspection of all those who may wish to study, or who may desire information as to the mineral products of the Pacific coast. When the collection becomes worthy of acceptance, it will be donated to the State of California upon the conditions that it shall not be removed from the city of San Francisco, that it be properly taken care of, and that it shall be placed on exhibition free to all.

The second purpose of the society will be to study geology and encourage others to do so. It has long been a reproach, that while the people of the Pacific coast have displayed such remarkable energy in the development of the mineral deposits which nature has provided so bounteously, little or nothing has been done to aid the prospectors, to whom the credit of their discovery justly belongs. Strangers, and especially foreigners, naturally ask, "Where can we see a State collection of your minerals?" to which there can be returned no answer. The prospector who wishes to study the types of the minerals and ores he is in search of, has no resource but to seek information from private collections to which he can gain access.

There is no class of men who so eagerly seek information or so seldom obtain it, as the miners and prospectors of the Pacific coast. They are naturally intelligent and often well educated. Love of adventure and the natural desire of mankind to seek new countries brought them early to the Pacific coast. To them we owe everything. Until they had paved the way we could not have lived on the sites of our most populous cities. Few can realize the difficulties and dangers they meet and overcome in opening up the wild, inhospitable regions over which they swarm. In conversing with them, their first expressed wish will be a desire to acquire a knowledge of geology and mineralogy. The eagerness with which they buy or borrow books, and the interest with which they read them, is an evidence of this fact. These men who have done so much for our State, and are doing so much, are certainly worthy of some consideration, and should be provided with the means of gaining the information they so much desire. A private collection thrown open to the public a few years ago attracted a large number of visitors, as the register will show.

Strangers who seek the new fields for manufactures offered by our State, naturally look to the country for the material upon which the proposed manufacture is based. For this reason the inquiry for iron, graphite, gypsum, cement, limestone, marble, clay, building stones, salt, emery, alum, baryta, manganese, slate, asbestos, mica, borax, nitrate of soda, sulphur, etc., is of almost daily occurrence. In the absence of anything like a State collection, they naturally—like the miners and prospectors—apply to the owners of private collections for localities of the much desired minerals.

Much has been done by private individuals toward the study of mineral products of the State. As some information concerning these collections may be interesting, I will give a brief history of them as far as I know:

The well-known Piche collection is one of the largest ever made on the Pacific. It was commenced by Mr. A. Remond, a young French gentleman of high attainments, who was devoted to the science of geology. When he died, Mr. Piche expended large sums of money in adding to it and in its arrangement. At his death, it became the property of the State University by his bequest.

A collection made by Mr. C. D. Voy has also passed into the possession of the University. This is really a remarkable one, and has more local value than any of the others. It consists of rocks, fossils, minerals, ores and ethnographic specimens of great interest, mostly from the Pacific coast.

My own collection, the work of many years, is also embodied in that of the University.

This aggregate, including the collections made by the State geological survey, and much museum matter acquired by purchase, is by far the best collection on the Pacific coast, and will compare favorably with those of similar institutions elsewhere. It is admirably suited to the requirements of the University. Among other collections I may mention the following:

One owned by Mr. Charles Schneider, of San Francisco, which is large and well selected. It consists of minerals only, but is very complete and valuable. It is especially rich in rare mineral species.

One at the Mercantile Library has many fine and beautiful specimens, almost wholly minerals.

Mr. Melville Attwood, a member of this so-

ciety, has a large collection, mostly geological, consisting mainly of rocks and ores. Mr. Attwood has given much attention to the microscopic study of the rocks, and has prepared sections of nearly all his specimens.

The Society of Pioneers have a collection of considerable value. The specimens are principally rich ores of gold and silver.

The California Academy of Sciences have large quantities of minerals, fossils, rocks and ores.

The collection of ores at the Occidental hotel is justly celebrated, but it has but little scientific value, although the ores are selected mostly for their richness in precious metals.

The St. Ignatius college, on Market street, has a small but well selected collection, nicely arranged, and of much scientific value.

At the Alta office there is a collection containing many beautiful and rare specimens.

A collection at the Bella Union theater is quite extensive, but it is not arranged upon any scientific plan.

Dr. Maxwell, of this city, has a fine geological collection, consisting of minerals, rocks, fossils and ores from Europe and the Pacific coast.

Dr. A. B. Stout is also in possession of a fine collection.

There are, no doubt, other collections in the city which are well worthy of mention, but I do not now recall them. Scattered through the States of California and Nevada, there are many local collections, showing the ores of the various districts, which are widely celebrated. They are generally the work of men who have no knowledge of mineralogy or the other branches of geology. The specimens are generally rich ores from noted mines. In making these collections the most interesting objects are generally overlooked.

It was a great mistake that the State Government did not give this subject more attention in the early days of California. During the last 25 years, the loss to science has been beyond calculation, from the failure to collect and preserve the mineral discoveries made by the miners and prospectors, during that period of wonderful activity. Had the proper collections been made, the State would have now possessed a collection identified with its history; of daily use to its citizens, and a contribution to science in a world-wide sense.

Modern geology has become a science to which all others are tributary. The history of the earth is the history of the universe. The same chemical and physical laws which govern matter here, govern matter beyond the fixed stars. This science is the slow growth of ages. The earliest historians noticed fossils and expressed wonder as to their origin. The ancients were surprised to find shells, perfect in form, imbedded in the solid rocks. Knowing nothing of geology, they could only account for them in two ways: either that the seas once covered the tops of the mountains, or that the supposed shells were not such in reality, but were only an accidental resemblance to shells. The traditions of Noah's flood, and the deluge of Deucalion, found strong confirmation in these discoveries. Ammonites were mistaken for petrified serpents, and the teeth of elephants for those of giants. Strabo uses remarkable language in writing on this subject, which would indicate that the ancients were not wholly ignorant of geology, as we understand it. The following quotation from the writer would not be out of place in a modern lecture on geology: "The real cause, I repeat, of all the changes is that the bed of the sea is sometimes accidentally elevated and sometimes depressed." In the year 1517, at Verona, the discovery of petrified shells and crabs caused much speculation among the thinking men of the period. One learned man, Fracastoro, boldly stated that these shells could not have been deposited by the deluge, for the reason that the rushing waters would have broken them or scattered them on the surface of the earth. He rejected, as absurd, the theory that they were not real shells, but the result of "plastic force." Without being able to explain how, he maintained that the shells died where they lived, and that the sea must have been at some time above the tops of the mountains.

The theory of "plastic force" took many forms, some stating that the shells were the sport of nature, or "stones in disguise," while others, leaning toward the belief in their organic origin, offered as a compromise the theory that they might have been ejected from submarine volcanoes and thrown upon the land. Palissy, a celebrated French potter and scientific man, revived the theory that fossils were the remains of marine animals, and being found perfect, with unbroken spines and edges, could not have been conveyed by water, but must have died where they lived. This was the birth of the science of paleontology.

The next important step in the growth of the science was made in 1740, when Marsili discovered that shells were associated in genera, which differed with the locality and with the formation in which they were found. In 1759 Arduino classified rocks into primary, secondary and tertiary.

Soldani, in 1789, began to use the microscope in the study of minute forms and in the classification of rocks. During the sixteenth and seventeenth centuries much was written on the progressive science of geology. The science slowly grew into importance, advancing step by step, each observer adding something. It was long considered a heresy to doubt the universal spread of the deluge over the whole face of the earth. Linnaeus boldly affirmed that such an event as the covering of the whole surface of the earth by water was impossible. He

showed that calcareous deposits had an organic origin, and proved that animal and vegetable matter combined with mineral matter in forming the earth's surface. In 1775, Werner promulgated his celebrated theory of the universal agency of water in forming the earth's superficial crust. Those who accepted his theory were known as "Neptunists," while those led by Dr. Hutton, who believed that the same phenomena was produced by fire, were called "Vulcanists."

Dr. Toulmin published a work, in 1775, "On the Antiquity of the World," in which he claims "that no single substance in nature is either permanent or primary; that animals, vegetables and minerals alike have their origin in the gradual progress of time, and that all matter is subject to innumerable transmutations and changes. The globe itself is subject to slow but important revolutions; that it undergoes incredible changes from heat and cold, volcanoes and earthquakes; that vast alterations are gradually made by the decay, generation and petrification of vegetables and animals. That the sea is continually altering the surface of the earth; that in the lapse of time it encroaches upon the land, and takes it from its inhabitants and restores it to them again."

In 1807 the Geological Society of London was organized. It originated at a meeting of a few scientific gentlemen who met for the transaction of other business. The birth of this society did much to advance the science of geology. Similar societies were organized in Europe, each of which did its share toward new discoveries in geological science. About this time William Smith, a surveyor and student of geology, developed remarkable talent as a geologist—so much so that he became identified with British geology, and for a time maintained the highest position. He not only made the first important collection of British fossils, but published the first geological map in 1815. From the date of his first map, Mr. Smith published no less than 20 geological maps of different parts of the British islands within the following 10 years. Before his death his extensive collection of organic remains became the property of the British museum, forming the nucleus for the paleontological collection of the present day.

The Geological Society now numbers nearly one thousand fellows, who reside in every part of the world. The museum of minerals, fossils, rocks, etc., not only British, but from all quarters of the globe, is very extensive. The society has published its transactions, and now issues a quarterly journal; their rooms are in the Somerset house, in the Strand.

The Museum of Practical Geology, in Jermyn street, London, was established in 1835. Sir Henry de la Bache, of the Geological Survey, called the attention of the government to the importance of making such a collection, the Geological Survey offering great facilities. The collections were at first placed in an obscure locality, but they grew so rapidly, principally by donations, that the present commodious and beautiful building was erected for their reception, at a cost of £30,000.

The following description of the museum is from a late Hand-Book of Modern London: "The collections illustrate the mineral products of every part of the United Kingdom and colonies, including the marbles, porphyries, building stones, etc., with complete series of fossils, ores and minerals. There are beautiful specimens of polished vases, statues, inlaid floors of mosaics, of native substances and manufacture. They comprise illustrations of the application of geology to the useful purposes of life; numerous models of mining machinery, metallurgical processes and other operations, with needful maps, sections and drawings, and a proper and comprehensive view of the general subject. Pottery and porcelain, a very good collection historically arranged. The lecture theater holds 450 persons, and evening lessons to workmen, illustrative of the collections in the museum, are delivered in every season. The collections are open to public inspection every week day except Friday."

Nearly every country of any importance is now or has been employed in geological surveys. Among the most notable are India, Australia, New Zealand, England, and, of late years, the United States. Most of the States of the Union have individually published reports of their geology, in which California is not behind. When the magnitude of the territory undertaken is considered, it is wonderful how much has been accomplished. One volume of general geology, two on paleontology, one on ornithology, and lately, one on botany, besides numerous excellent maps, have been published, which are a credit to the State.

The present state of geological science may be briefly summed up as follows: It is assumed, rather than proven, that the earth, in common with the other bodies of the planetary system, owes its origin to the condensation of nebulous matter. The heat which caused its attenuation became concentrated in the center of our system, and produced the sun. This theory is substantiated by the revelations of the spectroscopic, which proves that the sun and the nebulae are composed of identically the same elements which we find existing in the earth. The planets are supposed to have been rings of nebulous matter, somewhat concentrated by the same causes which produced the sun. These rings were broken up and further concentrated, forming the planets, of which the earth is one. As this matter became further condensed, the elements began to react upon each other, producing a red hot earth, surrounded by an

atmosphere of air mixed with aqueous vapors at a high temperature. As the earth commenced cooling, hot waters, highly charged with carbonic acid, fell, and chemical changes of a complicated nature took place on the earth's surface. As more and more heat was radiated into space, the water became cooler, and when the warm rains fell, a portion remained, forming seas and lakes, while the irregularities of surface became land. Countless ages must have passed before the lowest forms of plants could live. As the cooling of the earth progressed, the following events succeeded each other: Plants of higher orders grew luxuriously, covering the earth with dense vegetation. During this period the state of the atmosphere generated violent storms of wind and rain. The falling rains washed down parts of the more elevated lands and deposited the sedimentary matter in the beds of the oceans and lakes, giving rise to the stratified rocks. The vegetable growth, under the influence of the sunlight, began locking up the carbon of the carbonic gas largely in excess, and setting the oxygen free, thus purifying the atmosphere and rendering it fit for the use of animal life, which began to appear in its lowest forms.

The lowest stratified rocks enclosed the lower animal and vegetable forms then existing. We cannot conceive of the time that must have elapsed before the higher order of animals, including man, could exist on the earth's surface. Each successive age left its record in the stratified rocks which geologists now regard as an open book. Certain causes, which can be only generally stated, have broken up the horizontal strata so formed, and strangely distorted them.

It is generally conceded that the enormous weight of sedimentary matter deposited on one portion of the earth's surface caused other portions to rise. This, the cooling of the earth's crust, the attraction of the sun and moon and earthquakes, are favorite theories by which this phenomenon is accounted for. The falling rains, acting on the disturbed strata, produced a new class of sedimentary rocks, until finally the whole earth became enveloped in a coating of its own ruins. Sedimentary rocks, in many cases, have undergone change and have become metamorphic. The stratified rocks, no matter how much they may be disturbed, always retain the same relation to each other. Geologists have classified them and are studying them in every portion of the earth. It is assumed that their ages may be determined by the fossils contained in them.

This is only true in a general sense, for it is, I believe, admitted that in different parts of the earth at the present day, different species of animals and vegetables exist, as, for example, animals are now living in Australia and the South Sea islands, which are not found elsewhere; still the principles are correct, for geologists do not attempt to indicate the number of years or centuries which have elapsed during each geological epoch, but all dates and eras are relative. It is considered a mistake to suppose that geological changes have been necessarily a series of catastrophes, violent or sudden, but they have been gradual, the influences controlling the changes being as active now as they were countless ages ago.

The study of geology naturally assumes two forms—scientific geology and practical or economic geology. Scientific geology aims to complete the earth's history; to account for the varied phenomena which present themselves; to ascertain the chemical composition of the rocks and minerals; to classify and describe the fossils; to study their bearing on the history of the successive ages in which they lived, and to speculate on the future. Economic geology, on the other hand, has for its object the utilization of the various mineral products.

It seeks to develop new mines and invent new uses for the ores they produce; to analyze the soils; to bring to notice the various members of the mineral kingdom. Man cannot dispense with the supplies which he draws from the earth's surface. Take from him iron alone, and he becomes comparatively helpless. Deprive him of all the minerals of the earth, and he is only in intellect above the beasts of the field.

The bias of this society will be in the direction of economic geology. It will be its purpose to encourage the development of all and every mineral product discovered in the future, or already known. It will foster and aid in every way in its power legitimate mining and manufactures dependent on the minerals of our State. In this it will accept the Museum of Practical Geology of London as its model.

PURIFICATION AND DEODORIZATION OF PETROLEUM PRODUCTS.—Mr. S. E. Johnson, of Ashby-de-la-Zouch, England, has discovered a method of treating petroleum and other mineral oils, by which these liquids are not only purified, but also deodorized; and that in a simple and inexpensive manner. Chloride of lime is first introduced into the cask or other receptacle containing mineral oil or spirit, in the proportion of about three ounces of chloride, more or less, to each gallon of the liquid, according to the degree of its impurity, and thus chloride gas is evolved in the oil or spirit. If necessary, the evolution of the gas may be assisted by pouring in hydrochloric acid, agitating the content of the receptacle so as to bring the whole of the liquid into intimate contact with the chlorine gas. The oil or spirit is then passed into another enclosed vessel containing slaked lime, which, having an affinity for the chlorine, absorbs the same, leaving the liquid sufficiently deodorized and purified.

Mines of Great Britain.

A precise knowledge of the extent of the products of the metalliferous mines of the United Kingdom, and of the great industries dependent upon these products, may be gathered from the following statistics: The pig iron produced from British ores during the year 1875 amounted in weight to 6,365,420 tons, and its value at the places of production equaled £15,645,774. Of copper, 4,322 tons were raised, valued at £388,983. Copper and silver precipitate amounted in quantity to 54 tons, and in value to £3,207. Tin was gained from "the bowels of the harmless earth" to the extent of 9,604 tons, of which the market price was £666,266. Of lead, 57,435 tons were extracted from the mines of that metal, and these represented a money value of £1,290,373. Zinc came up to the tune of 6,713 tons, and produced the sum of £162,790. Silver extracted from lead gave 487,358 ounces, at an estimated value of £115,747, while the gold obtained from the auriferous rocks of Merionethshire and from the mines of Hlogon and Cape Coch amounted in the aggregate to 584 ounces, and these were valued at £2,105.

A general summary brings the grand total value of minerals (including coal) and metals obtained from the mines of the United Kingdom during the past year to £67,487,688. When the returns for the current year shall be made up it is quite possible that, despite the depression in the metal trades which has distinguished 1876, the total yield of minerals and metals will not fall far short of its predecessor. It will probably surprise some persons to learn that in 1875 no less than 5,061 tons of arsenic, worth in the market £31,174, were thus yielded. Much of this rather suggestive and not very reputable mineral, it may be explained, is used in processes connected with the arts and manufactures of the country, and not for sinister purposes. Of manganese, 3,205 tons, equal in value to £15,906, were raised. Ocher and umber combined gave a total weight of 5,315 tons, and, in all, produced the sum of £7,185. Of wolfram and tungstate of soda, 48 tons were obtained, equaling in value £362. In the matter of plumbago—the whole of which is the net product of the Borrowdale mine in Cumberland—20 tons were extracted. It is impossible to give an estimate of the value of this substance, either in its natural or manufactured state, for the whole of it is retained by the Plumbago mining company itself for the manufacture of the "Real Cumberland" black lead pencils. In the way of fluor spar 359 tons, of the value of £188, were brought to the surface and disposed of. Clays (porcelain and fire clays) exhibit an aggregate total of 3,008,444 tons, fetching £753,957; oil shales amounted to 442,336 tons of the value of £200,000; while salt is responsible for a weight of 2,316,644 tons and a sum of money equal to £1,158,322. Barytes came up to 15,549 tons, valued at £14,089; coprolites rose to 250,122 tons, rated at £528,000; while sundries added £3,500 to the sum of the miscellaneous items just enumerated.

At the Furnaces.

The enormous slag piles that grace the neighborhood of our furnaces stand in the same relation to our mines as the tailings of the stamp mills do to the free milling ores, with this one unfortunate difference, that, while the tailings can be reworked cheaply and the precious metals extracted, no process can do the same for the slag at a rate that will give any profit. The slag pile represents a waste of from eight to 10% on all the ore smelted, and carries quite a percentage of lead and silver. It is roughly estimated, that the dump at the Eureka Consolidated contains at least \$1,000,000 of the precious metals, and the Richmond as much more. As great quantities of this material has been used to fill up our streets we can boast that they are literally paved with silver, and we doubt not but that a sample of dirt from Main street would yield a good assay. Our citizens are familiar with the picturesque sight at the furnaces where the molten stream is constantly pouring into the iron pots from the hearth. The specific gravity of the lead and its affinity for silver carries those metals to the bottom of the furnaces. On the top of these float the lighter impurities of the ore, consisting of silica, etc., and technically termed slag. The hearth is provided with two spouts, one some three inches higher than the other. The top spout is continually running and carries off the slag, which is wheeled away and forms the principal component of the dump pile. At intervals the lower spout is tapped, the melted iron run off, and the cubical castings that ornament the surface of the slag piles are the result of this operation. The smelters exercise great care in handling the iron, as in cold or damp weather the least moisture coming in contact with it will produce a violent explosion, scattering the molten mass in all directions. At the side of each furnace there is a receptacle, called a lead well, communicating with the bottom of the furnace by a pipe running into it. The melted lead runs into the well through this pipe, and is ladled out into molds, forming bars, averaging 115 pounds in weight. This is the base bullion in a form ready for refining. The time may possibly come when the refuse of the furnace can be utilized and reworked, but at the present cost of smelting there is no probability of such a process. In the meantime it can be used to grade and repair the streets, and its merits in that direction are too important to be overlooked.—Eureka Sentinel.

Practical BOOKS

—AT—

BANCROFT'S.

A. L. Bancroft & Co. keep on hand a large stock of American and European Books, Suitable for

CIVIL ENGINEERS,

FARMERS,

MACHINISTS.

And Industrial Classes generally, and supply them, post free, at published prices; for particulars of which, see catalogues, which will be forwarded on application.

\$1,000 Challenge Ore Feeder,

AWARDED FIRST, PREMIUM

At the Tenth Industrial Fair of the Mechanics' Institute.

It may be considered as now fully demonstrated, by careful and long-continued experimentation, that the plan upon which a perfect ore feeder must be constructed is that of the carrier, and not that of the shaking table. Uniform and accurate feeding is not possible upon the latter plan. The ore must be evenly carried, upon a steadily advancing plane or table, to the line of discharge, and there simply dropped. Spasmodic or jerky contrivances will not answer the purpose.

REFERENCES.

A letter received from the Julian Mill, Newcastle, says of the Carrier Feeder: "It is the most perfect Feeder we have ever seen; don't see how any mill can do without them." A letter from Mr. C. C. Belding, of Amador County, speaks in the highest terms of them. Two of the machines were shipped to the Bunker Hill Mill, also Dover Mill, Amador County. Mr. Stevenson, of Boston Mill, Gold Hill, Nevada, says they are the best Feeder he has ever seen. Soulsby Mill, Tuolumne County. California Company, Nevada City. Omaha Gold Mining Company, Grass Valley. St. Patrick Mill, Placer County.

\$1,000 CHALLENGE.

Backward in Coming Forward.

C. P. Stanford Fails to Come to Time on the Challenge of \$1,000 to Test the Merits of His Ore Feeder as Against Mine. The Challenge is Still Open to Him or any one else. GENTLEMEN, Put up or Shut up.

A letter has been received from the Crescent mine, Plumas County, in which it states that the Tulloch is a failure as against the \$1,000 Challenge Feeder of Hendy's.

We warrant the machines to give perfect satisfaction, and to be a better and more durable Feeder than any other in the market, and will sell them as cheap as any other of its class.

Has Padded from all others, is cup-shaped, with Self-Adjusting Ball in center, adapts itself to all positions of the body, while the Ball in the cup presses back the intestines just as a person would with the finger. With light pressure the Hernia is held securely day and night, and a radical cure certain. It is easy, durable and cheap. Sent by mail. Circulars free. ECCLESTON TRUSS CO., Marshall, Mich.

The Mining Debris Decision.

We print in full below the decision of the jury in the mining debris case (Atkinson vs. Sacramento and Amador Canal Co.,) and Judge Sexton's

Instructions to the Jury.

Gentlemen of the Jury: The attorneys for the plaintiff and defendant have presented so many special instructions, that but little has been left for the Court in general instructions.

And first we will endeavor to clear the case of some of the clouds which have been attempted to be thrown around it.

Upon the question of title, which has been so largely dwelt upon, the Court instructs you that with the question of title, in its purely legal sense, you have nothing to do. If the plaintiff was in the actual possession of the land described in the complaint under claim of title, then he has sufficient right to maintain this action.

Again, it is a matter of no moment in this action that some person other than the defendant would probably have flowed tailings and sand and gravel upon the land of the plaintiff, for the reason that it cannot in any wise be a justification to defendant, nor can it be urged as an excuse, or in mitigation of damages. A prospect of what others might have done in committing a trespass is no excuse or justification of a trespass committed by defendant.

Instructions Asked by Plaintiff.

The following instructions asked by plaintiff were given:

First.—If the jury should be satisfied from the evidence that the plaintiff's lands were damaged from the deposit thereon by the defendant of the gravel, sand, mud and other debris known by the general name of tailings, they must find a verdict for the plaintiff for the amount of damage which the plaintiff has sustained thereby, notwithstanding the defendant may have worked its mine after the manner customary among miners; and notwithstanding the fact, if it should be so, that the mine could not be worked at all without doing much damage to the lands of plaintiff.

Second.—The defendant has questioned the legal title of plaintiff to certain portions of the land in his possession claimed to have been damaged by the deposit from defendant's mine, but has not connected itself with the title to any such portions; as it is not disputed that defendant has ever since 1870 been in the actual possession, by inclosures, of all the land claimed to have been damaged (except a small fraction thereof) under claims of title thereto, it is not necessary to inquire into such disputed title; and the amount of damage to which plaintiff may be entitled will not be affected thereby.

Third.—If you find for the plaintiff, then in estimating his damages you will calculate the difference between the value of the land in issue on the 30th day of March, 1875, in its then condition, and its value as it would have been on that day if uninjured as alleged in the complaint. In this connection the value of the land includes the value of fences, ditches, dams and the improvements upon the land; and in estimating the injury done to the land, you can include the injury done to such improvements.

Fourth.—To acquire a right by prescription to overflow the lands of another with water, sand, mud or tailings, there must have been an actual occupation by such overflowing under a claim of right for five years, and such occupation must have caused damage to the knowledge of the injured party, and there must have been during a period of five years such an occupation and damage as will raise a presumption that the injured party would not have submitted to it unless the other party had acquired a right to use it.

Fifth.—Preponderance of evidence is the result which is produced upon the mind, not merely by the number of witnesses testifying upon one side or other a disputed state of facts, but by the weight of conviction produced by such testimony, having regard to the intelligence, impartiality and acquaintance of the witnesses with the subject matter testified about; so that preponderance of evidence may be, and often is, effected by a few witnesses against many witnesses.

Sixth.—Defendant has not acquired the right by prescription to use plaintiff's land as a place of deposit for tailings, nor has defendant acquired such right under any act of Congress.

Seventh.—To acquire a right by prescription to do acts injurious to another's property, the injured party must have assented to a commission of such acts by the party committing them, continuously for five years. By assent, you may understand an implied or actual assent, an avowed or a tacit one—a knowledge of the acts done, without objection to their being done.

Eighth.—In weighing the evidence you should consider the manner of the witnesses upon the stand, their probable motives in giving their testimony, and their opportunities for obtaining accurate information as to the matters concerning which they testify; and if the testimony of two unimpeachable witnesses as to any particular is in conflict, then the testimony of the witnesses who appear to you as the most intelligent, and whose means of observation have been the most favorable, and who have made the most careful examination of the subject of the testimony, is entitled to credit, when it ac-

cords with the other facts and circumstances of the case.

Instructions for the Defendant.

The defendant asked, and the Court gave the following instructions:

First.—The plaintiff is not entitled in this action in any event to recover the rents and profits of the land.

Second.—The plaintiff must prove the facts necessary to his recovery herein by a preponderance of evidence. If the evidence is evenly balanced, or preponderates in favor of the defendant on the material issues, your verdict in that event must be for the defendant.

Third.—The burden of proving what would have been the value of the land had it not been covered up is upon the plaintiff. If the evidence leaves the matter evenly balanced as to whether the land was more valuable before the deposit upon it than after, then you must find upon that point for defendant.

Fourth.—If the plaintiff's land has been improved instead of injured by the deposit, then you cannot find more than nominal damages in favor of plaintiff. By nominal damage is meant some small sum, such as \$1. By being improved means, in this connection, that its actual cash market value is greater now than before the deposits were placed upon it.

Fifth.—If a person destroys an acre of land belonging to another, the owner of the land can recover the value of the land at the time of the destruction, with legal interest from the time of the destruction. He cannot recover the value of the use and occupation of the land.

Sixth.—If persons other than the defendant, and having no connection whatever with the defendant, have caused any portion of the injury to the plaintiff's land, the defendant is not responsible for the portion of injury so caused by such other persons.

Seventh.—The jury, in estimating the damages, cannot take into consideration any depreciation in the value of any part of the plaintiff's land not damaged by the act or acts of the defendant, but in estimating the value of the valley land, you should fix its value in connection with the adjoining lands, both prior to the placing of the deposits upon it and after.

Eighth.—(Modified by the Court from an instruction asked by defendant.) If the defendant discharged in the usual and ordinary working of mines, water, tailings, earthy and other matter upon the banks of Arkansas creek, at places remote from plaintiff's land, and such matter, in the course of nature and from the effect of natural floods, flowing in and down said creek, found its way down the creek and was deposited, portions of it, upon plaintiff's land, the defendant would not be liable to damages—but if the deposit of sand and gravel and sediment was carried directly upon the lands by the water used in the mine; or, if the deposit of sand, gravel and sediment was deposited in such close proximity to the land that it must of necessity pass upon the land of plaintiff, the defendant would be liable for all damage done by defendant.

After an absence of three hours, the jury returned into court with a verdict for plaintiff and damages assessed at \$4,000.

A stay of proceedings for 60 days was granted.

The Belcher Mine.

The annual meeting of the Belcher mining company was held on Tuesday last, and the reports of officers for the year received. The Secretary's report does not show a very flattering condition of affairs. The mine produced last year \$2,920,460 in bullion, and one would suppose that that amount of production would warrant payment of dividends, but only \$416,000 was paid; in fact, a \$1 assessment is expected. These figures are rather discouraging to others who expect dividends from mines on the Comstock which produce less than this.

The bill for crushing ore alone was \$1,534,924, which will indicate what a good thing it is to own a mill in that vicinity. This was for crushing 131,328 tons of ore, which yielded an average of \$22.23 per ton. In any other part of the world this would be considered first class ore, and the bullion yield of the year—nearly \$3,000,000—a first class product, but it seems not to have been very profitable in this instance.

From the Superintendent's report we extract the following: For the year ending December 31st, 1876, there was extracted and shipped to the mills for reduction 131,228 tons of ore. This ore was extracted from the various levels above the 1600-foot level, and principally from the east and west streaks outside the main ledge. An attempt was made to work the fillings, but the result proving barren, it was abandoned. On the 1500-foot level the ore is not of the quality which will pay for extracting, although the ledge upon this level retains its regular course and width. Cross-cuts run at different intervals on this level developed no ore which would pay for extraction. A drift run to the south line and a cross-cut run east shows a fine body of quartz. The 1600-foot level drift cuts the vein 618 feet south of the north line. This drift shows a fine quality of quartz. A drift has been run south to the Seg. Belcher line. Cross-cuts made at different points resulted without the finding of ore. The main incline is down 100 feet below the 1600-foot level, and as soon as it reaches the 1800-foot level a new station

will be opened. The air shaft has attained a depth of 1,850 feet. When the pumps are lowered, a station at the 1800-foot level will be opened, and drifting and cross-cutting on the vein will be commenced. During the past year 3,270 feet of drifts were run; 1,012 feet of winzes and inclines sunk. Large improvements and additions were made to the surface buildings and machinery. The 131,328 tons of ore worked produced \$2,920,461, being an average yield of \$22.23 per ton.

The Secretary's report we publish in full:

Items of Interest from the Mines.

We give below items of interest from prominent mines, most of which are collated from letters of the respective superintendents on file at the offices in this city. Considerable of this news is later than that procured from the interior journals:

The last official letter of the Ophir company is not very encouraging. It says: Since stopping the mills have reduced the force of men in mine very much, also all expenditures. The remaining ore on 1465, 1600, 1600 and 1650 levels is so poor it would not pay for mining; have, therefore, quit all work in the ore breasts on those levels; on the 1650-foot level have a limited quantity of fair ore, average assay about \$30; raising about 15 tons per day; when sufficient quantity has accumulated in ore dump, will ship to one of the mills.

In the ninth level of the Eureka Consolidated the ore body is looking very favorable. The upraise and winze when attaining the height of 40 feet opened into a large natural cave extending up to the eighth level. Have found a fine quality of ore in cave, the top and sides of which seems to carry more or less ore. This natural opening will save the labor of raising winze in making connection with the eighth level.

In the Raymond & Ely mine the prospect work being prosecuted above seventh level is showing some promising vein matter, but assays run low. The mills are still idle; as soon as the weather moderates will start up the 30-stamp mill and run through the tailings, which will yield a good profit.

The superintendent of the Gould & Curry in his last letter says: On the 1,700 level the ground in the east drift was so difficult to keep up and the heat was so great that but little progress could be made, so I concluded that it would be economy to prospect ahead with a diamond drill. We have bored 52 feet from the face through blocky porphyry; samples have been taken from every ten feet but so far without any result.

The Belcher air shaft has now attained a depth of 1,873 feet.

The Justice ore-producing stopes throughout the 400, 500 and 600-foot levels continue to produce their uniform grade milling ore. Ore developments in Nos. 1 and 2 crosscuts, as well as north drift on the latter level, are developing a regular and well-defined body of ore. The 700-foot level north drift has met with a marked improvement in discovering important body of ore, the like of which and the general character of the ore produced is different from anything hitherto found on this level. Further explorations are necessary before its extent can be known.

The superintendent of the Golden Chariot (Idaho) writes rather encouragingly. He says the 1300-foot level is now in a distance of 108 feet. The vein continues wide and is producing better ore than at any time heretofore. Its great width and the increased value of its ore as it approaches the ore chimney affords proof of the value of the result.

On the 1500-foot level of the Consolidated Virginia the various ore breasts are looking well and yielding the desired quantity of ore. East of the main ore body we find a spur of ore 27 feet in width. Its course is not east. The quantity of ore is good, all of which assays over \$100 per ton. The separation between this and the main ore vein is from 11 to 20 feet of hard blasting rock. On the 1400-foot level the ore breasts are looking very favorable. Lower levels are much cooler, owing to the enlargement of the 1500-foot level drift. This work is not yet completed.

Home Manufacture of Agricultural Implements.

The manufacturing industry of our young State is strong and promising. The great shops of our city build some of the most ponderous and intricate machinery which the mechanic has contrived. Scattered here and there throughout the State are the local manufactories, which furnish many valuable implements and tools. Here and there, too, are flour mills and woolen mills, either now in active operation or projected by enterprising men. All these things are marks of the State's progress, and we would have them multiplied until our State shall furnish altogether its own manufactured goods, and support a thriving manufacturing population, giving active home markets for our large agricultural production. There are indications that this advancement is being made, and we refer with pleasure to one outcropping of the progress which is announced from Sacramento. We learn that a few days since there were filed in the County Clerk's office articles of incorporation of the "Sacramento Manufacturing Company," with C. T. Wheeler, of Booth & Co.; R. S. Carey, ex-President of the State Agricultural Society; Robert Hamilton, of Baker & Hamilton; Christopher Green, of Green & Trainor; Albert Gallatin, of Huntington, Hopkins & Co.; E. B. Mott, Jr., formerly of Gillig, Mott & Co.; J. M. Keller, of Keller & Co., incorporators. The object of the company is to manufacture all kinds of agricultural implements used in this State and on the Pacific coast generally.

It is interesting to note some advantages which these enterprising men foresee in the competition which they will have to enter with Eastern manufacturers. A reporter who questioned Mr. Hamilton gained these among other points from him:

The dry climate of the interior region is the most favorable known for the manufacture of goods made in whole or in part of wood. The timber becomes so well seasoned by the atmosphere that if it is dry at all when it is made up, and it soon dries, it does not shrink after working, so that really articles of this class made here and from the same material and by the same workmen would be much more valuable, because more durable, than if manufactured in the moist climate of the East or anywhere on the sea coast. All our experience proves this, and the farming public are well acquainted with that fact.

The cost of freight on this class of goods from the East to California is a large item. On bulky articles, such as threshers, headers, cultivators, plows etc., the freight would amount to nearly or quite one-fourth the market value of the goods at this point—which would be equal to 25 per cent. in our favor. Again, a car load of manufactured goods such as we propose to make would cost for freight a given price, while a car load of unmanufactured goods would cost 25 to 40 per cent. less according to the class; and in addition, while it would be next to impossible to put ten tons weight of these manufactured goods into a car, it will readily contain full ten tons of the raw article. And if goods were to come by sea the proportion would be about the same. This is the law or the rule of all transportation companies, or, in other words, the law of trade. Then the manufactured goods, such as reapers, mowers and the like have to be boxed at a cost of \$20, and often \$30, and we have to pay freight on the box, besides paying for its cost. This saving on freight and boxing alone would be a fine profit for any such establishment in California, and is sufficient in itself to exclude Eastern manufacturers from underselling us, however cheap their capital may be. And I may say in addition that we can procure the best of Oregon ash laid down here at \$30 per M—and this is just the material for heavy machinery. This ash and Oregon pine are the principal woods we require, and in fact all we require for threshers, headers, harrows, cultivators and the like. For wagons and many other things we would require imported timber—but the bulk of our timber would come from Oregon. There is also another advantage which is often overlooked, but which is in fact and ought to be considered a prominent factor by those who enter upon enterprises of this kind—it will give steady employment at good wages to hundreds of our people—to those who live among us. That is one thing that California much needs—for the wealth thus distributed returns in time in one mode or another, if not in whole, then in part at least, to those who distribute it.

We hear also that a movement for home manufacture is undertaken in San Jose. It is said by the *Washington Independent* that a number of leading mechanics propose to establish a manufactory for constructing all kinds of agricultural implements at the Alameda foundry. This is between San Jose and Santa Clara, on the line of the new narrow-gauge railroad from Dumbarton point to the Santa Cruz mountains, which will deliver iron, coal, lumber and all other material where needed, at low rates. The company aim to supply farmers with all the tools they need from a garden rake to an improved straw burning engine. About \$50,000 are already subscribed, and as much more is expected before starting the enterprise.

or reservation, as I should certainly prefer to entrust my own business in your hands should I have any to transact in the same line hereafter. Yours, etc.

THE O'HARRA

CHLORIDIZING FURNACE

Guaranteed to Chloridize from 85 to 95 per cent. of any gold or silver ores that are not more profitable for smelting. Will also desulphurize ores and put them in proper shape for working in cupola furnaces.

Cost of Roasting and Chloridizing by this Process:

Two cords of wood at \$6.....	\$12.00
Two firemen at \$4.....	8.00
1,500 lbs of salt at 1¢.....	22.50
Wear of shoes and power.....	1.50
Cost for 15 tons.....	\$44.00
Cost for one ton.....	2.93

In a furnace of three or four times this capacity the cost is decreased by 20 per cent.

The furnace is now working successfully at the Poe Consolidated Co.'s mines, in the Peavine District. For further information, apply to

D. J. O'HARRA,
Reno, Nevada.

The Ingersoll Rock Drill

Is Extensively Used in the East and

TAKES THE PLACE OF ALL OTHERS,

Wherever introduced, because it can be run with less power, labor and repairs, and do more work than any other Drill in the market. It has but few parts, is easily handled, being light, and has AUTOMATIC FEED, which saves labor. WE ASK FOR TRIAL AGAINST ANY COMPETITOR. For particular information regarding Drills or Air Compressors, send for circular to

THE ASBESTOS PATENT FIBER COMPANY,

TWO MEDALS OF HONOR.

HIGHEST MERIT.

Of Philadelphia, offer for sale through their agent in
San Francisco,

Asbestos Steam Packing, Asbestos
Boards and Asbestos Steam Joints,

All manufactured from the pure utilized Asbestos Pat-
ent Fiber, and under patents granted to J. S. Rosen-
thal. The packing is in all sizes from one-quarter to
three inches in diameter, round, and free from all grit
or mineral matter. The non-utilized or crude Asbestos,
manufactured by some parties into packing, is impure
and gritty, liable to injure the piston rod and should
not be used. The packing made under the Rosenthal
patents is of pure utilized Asbestos fiber, and a very superior article and entirely different from the so-called Asbestos
packing heretofore offered for sale. It is compact in form, will not fuzz or disintegrate, and will wear much longer
than any other kind of packing. The indestructible, expanding, contracting and lubricating qualities of Asbestos
are now universally recognized, and packing made from it is peculiarly adapted for steam engines and pumps.

ASBESTOS PATENT FIBER BOARD.

This is the champion non-conductor, to prevent radiation of heat and condensation of steam, as covering for
marine, stationary, or locomotive boilers and pipes, and for lining wood-work, where exposed to great heat. It is
light, flexible, is not disturbed by vibration, and will not char or crumble. The sheets are 30 by 44 inches, of any
desired thickness, and are easily applied.

ASBESTOS PATENT FIBER STEAM JOINTS.

Indestructible by fire or water, expands and contracts in a desirable manner, adjusts itself to any rough points
is cheaper than rubber, and in all respects a superior article. PURE ASBESTOS FIBER for packing steam gov-
ernors and other purposes. All these goods are extensively used in the Atlantic States and give general satisfaction.

Also, For Sale by

DEWEY & CO. American & Foreign Patent Agents

OFFICE, 224 SANSOME STREET, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent Reissues taken out Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Baden, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Granada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule price for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) SOONER than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more correctly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing to them the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

PICKERING ENGINE GOVERNOR.

VALLEJO FOUNDRY, October 17th, 1876.

Messrs. NEYLAN & YOUNG, San Francisco,

Agents for "PICKERING GOVERNORS."

Gents:—The 10 two-inch Improved Speed Adjusting Governors I bought of you this year for my patent Straw Burning Threshing Engines give splendid satisfaction. They far surpass for regularity of speed any Governor that I have ever seen, and I have seen all the best kinds; I have seen the main belt fly off the pulley several times this season while threshing, and the engineer did not discover it, so perfectly was the speed maintained, until he was told of it; this I consider something wonderful; I consider the Governor absolutely perfect, so far as speed is concerned. I bought and put on to one of my engines a Shive Governor, to see which was the best, and after one season's trial I have no hesitation in saying they are superior to any other Governor that I have seen or used. I wish you would send me the lowest price that you can furnish 25 Governors for next season's engines. Yours respectfully,

J. L. HEALD.

The only Governor that has received awards at each of the International Exhibitions. American Institute Fair, New York, 1865, Two Medals; Mechanics' Institute Fair, Baltimore, 1865, Silver Medal; American Institute Fair, New York, 1869, Two Medals; International Exposition, Paris, 1867, One Bronze and Two Special Medals; International Exposition, Vienna, 1873, Medal of Progress and Decoration; International Exhibition, Philadelphia, 1876, Medal and Diploma.

UNITED STATES Mineral Land Laws, Revised Statutes, AND INSTRUCTIONS AND FORMS UNDER THE SAME.

We have just issued a pamphlet containing the General Mineral Land Laws of the United States, with instructions of the Commissioner of the Land Office. The contents of this pamphlet comprise all of the Government laws with relation to mineral lands of interest to the mining community, as follows: Mining Statute of May 10th, 1872, with Instructions by the Commissioner of the Land Office; Mining Statute of July 26th, 1890; Mining Statute of July 9th, 1870. Forms required under Mining Act of May 10th, 1872, as follows: Notice of Location; Request for Survey; Application for Patent; Proof of Posting Notice and Diagram of the Claim; Proof that Plat and Notice remained Posted on Claim during Time of Publication; Registers' Certificate of Posting Notice for Sixty Days; Agreement of Publisher; Proof of Publication; Affidavit of \$500 Improvements; Statement and Charge of Fees; Proof of Ownership and Possession in Case of Loss or absence of Mining Records; Affidavit of Citizenship; Certificate that no Suit is Pending; Power of Attorney; Protest and Adverse Claim; Non-Mineral Affidavit; Proof that no Known Veins Exist in a Placer Claim, etc. There is also given the U. S. Coal Land Law and Regulations thereunder. The work comprises thirty pages, and will be sold, post-free, for 50 cents. It should be in the hands of every one having any mining interests. DEWEY & CO., Publishers of the MINING AND SCIENTIFIC PRESS, S. F.

KUSTEL'S CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arsenurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams, 1867. The most complete treatise. Published at this office. Price, \$5. Postage, 50 cts. extra.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS Office, S. F.

BY GUIDO KUSTEL,
MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their respective Metals without Quick-silver. 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in his specialty.

Price, \$2.50 coin, or \$3 currency, postage free.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arsenurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. PRICE REDUCED TO \$5.

Testing and Working Silver Ores.

The above is the title of an illustrated work of 114 pages, for miners and prospectors, by Chas. H. Aaron, which has just been issued by Dewey & Co. Mr. Aaron has managed to give many useful hints and suggestions, free from all technicalities, and in such a style as to be easily comprehended. It is written for the miner, with no chemical symbols or metallurgical technicalities to confuse those who are not chemists or metallurgists. The following summary of the contents of the work will give an idea of its scope.

Under the heading of the first chapter, "Testing Ores for Silver," we find paragraphs on ore formation, test for silver, with heat and water, acid or blow pipe. In speaking of testing for a process, the extent and richness of ore is considered, smelting ores, selecting and working sample, appliances for testing, roasting and under the head of "Working Ores" the author describes Aaron's process, has something to say of superheated steam, preparation of dichloride of copper and protochloride of copper, use of copper and iron, quantity of chemicals, carbonate of lime, chloride ores, amalgam, Patchen's process, etc. He also describes the methods of working roasted ores, treatment of base metals, stirring, heat of furnace, want of sulphur, etc. Under the head of "Leaching Processes" are the titles, Smelting, Mexican process, Chilean process, Kroehnke's process, etc. Under "Pulverizing Machines" are described the arastra and its construction and operation, stamp batteries, screens, Crocker's trip-hammer battery, Paul's pulverizing barrel, Kendall's battery, Noice's pulverizer, a cheap rock breaker, etc.

In speaking of amalgamators the author describes a cheap amalgamator, grinding the ore, directions for making a barrel, preventing mechanical wear, use of quicksilver, copper in bars, Freiberg barrel, cheap barrel, trough, barrel on rollers, Aaron's amalgamator, separator, etc.

He describes an improved retort, roasting furnace, furnace tools and furnace building. Among the miscellaneous mention may be found Aaron's leaching apparatus, with two or three different arrangements, a small mill, sampling tailings and settling tanks, dichloride of copper, etc. Mr. Aaron is a practical miner, of long working experience on this coast.

The book is a serviceable one for miners and prospectors' use. Price, post free, (in leather,) \$2.00. Address Dewey & Co., MINING AND SCIENTIFIC PRESS, 224 Sansome Street, San Francisco.

Much Obligated, Etc.

PORTLAND, OREGON, June 26th, 1876.

DEWEY & Co., Patent Solicitors, S. F.—Gents: I am much obliged to you for courtesy shown me, and am well pleased with the manner in which you have done my business, and assure you, will cheerfully recommend you to my acquaintances needing such services. Hope to have a case again before long, of my own. I have been an inventor all my life, but let others reap the benefit, or had work sent from them. Please have the extra copies of my patent, etc., mailed to me direct, and oblige. Yours truly,

J. H. WOODRUM.

SUTTER CREEK, February 26th, 1875.

Comstock Papers.—No. 16.

Pan Amalgamation, and What It Led To.

The trial of pan amalgamation having proved a success, demonstrating the facility and cheapness with which the Comstock ores could be worked, confidence in the value of the mines was greatly increased, and many parties were encouraged to put up reduction works who would not otherwise have gone into the business. The popular idea that a vast deal of science, or at least much practical skill, was indispensable in the treatment of argentiferous ores having been thus partially dissipated, the California millmen were quite certain that they could deal with them successfully when a method so similar to that employed in reducing the gold-bearing quartz of this State would answer the purpose. Accordingly a good many of this class repaired to Washoe during the summer and fall of 1860, with a view to putting up mills and running them on this new school of ores. The arrastras that had been set up the year before were designed merely for working the quartz found at Gold Hill, in which the most of the gold was free and easily separated, no effort having been made to save the silver which it contained; the miners not then suspecting, in fact, that it carried any of this metal. When the sulphurated silver ores of the Comstock proper came to be handled, this style of apparatus was found to be wholly inadequate; hence early recourse to more effectual methods became necessary.

Era of Active Mill Construction

The completion in August, 1860, and the successful operations of the Paul and the Coover mills, was immediately followed by the inauguration of numerous other enterprises of this kind, several having, in reality, been planned prior to the above date and in anticipation of the success that it was expected would attend these pioneer establishments. So rapidly, indeed, did this business of mill construction thereafter proceed, that no less than 86 works of this description, carrying a total of 1,200 stamps, and costing an aggregate of over six million dollars, had been finished and started up by the end of 1861, some 40 or 50 arrastras and several patio yards built and set at work meantime, not being included in this estimate. Work upon a good many other mills had also been commenced before the end of that year, the most of which were completed early in 1862, when the era of most active mill construction terminated in so far as the Comstock mines were concerned, this industry having, for the next three or four years, been transferred to Esmeralda, Reese river, Pine Grove, Humboldt, and other interior districts.

Location, Cost and Capacity.

Of the mills built for reducing the Comstock ores eight, carrying 114 stamps and costing \$200,000, were located in Ormsby county; six, carrying 106 stamps, and costing \$1,200,000, were located in Washoe county; forty, carrying 573 stamps, and costing in the aggregate \$3,700,000, were located in Storey county; twenty-two, carrying 360 stamps, and costing \$1,000,000, were located in Lyon county, and ten, carrying 84, and costing \$300,000, were located in Esmeralda county, there having been erected, up to the end of 1861, not more than two or three small establishments of this kind in any other portion of Nevada Territory.

The First Parties to Put Up Water-Driven Machinery.

East of the Sierra, for the purpose of ore reduction, were Judge James Walsh and his partner, Joseph Woodworth, who, on their first visit to Washoe, in the latter part of June, 1850, threw a slight dam across the Carson river, at a point about one mile above the present town of Dayton, then Chinatown, and, diverting the water into a side race, employed it for propelling a couple of arrastras, which they constructed and put up there for testing the Gold Hill ores, they having bought from Comstock a small claim at that point before purchasing the silver bearing deposit a mile further north, and which afterwards constituted the site of the great Washoe discovery. The water right so secured on the river was, the

next year, further utilized by the construction there of additional arrastras and, finally, by the erection of extensive reduction works, this now being the site of the present Ophir company's large and efficient mill.

Besides Paul, Coover and Harris, the following parties commenced the erection of mills, and, in some cases, completed and had them running before the end of 1860: Richard Ogden and J. Downes Wilson, who, in November, 1860, finished the Ogden & Wilson mill, the first one completed in the Virginia City district; Henry G. Blasdel, Alphens Staples, Israel W. Knox, who built the Olive Branch mill, Flowery district; McNulty, who built what was afterwards known as the Bacon mill; Peter Frothingham, who put up a small establishment on Carson river, four miles below Dayton; John B. Winters, connected with Woodworth & Mosheimer in the building of the Carson River mill; John Atchison, Logan and Holmes, whose works were also on Carson river; Trench & Sparrow; De Land, Eclipse mill; and various other persons, whose names we cannot now recall to memory. Among the mills that were begun this year and completed near the end of it or early in 1861, was that of the Spanish

Flexible Power Transmitter.

This is a very simple and useful device, as the accompanying illustration will show. It is the first successful application of a flexible shaft for general purposes of transmission of power. The *Polytechnic Review*, during the late exhibition, thus described this piece of mechanism: Passing along the north avenue of machinery hall, our attention was attracted to what appeared to be a section of inch leather hose, with a revolving twist drill for a nozzle, the hose lying quietly on the floor and the drill or nozzle making a clean, smooth hole through a chilled car wheel already perforated several times by the same means.

Following the "hose" backward and around a corner it was seen to terminate in the arbor of a rapidly revolving grooved pulley fastened temporarily to the floor and driven by a braided round leather belt, which after several corner turnings is seen to be driven by a grooved pulley high overhead. The mystery was explained.

THE STOW FLEXIBLE POWER TRANSMITTER.

company, at Virginia City; the Aurora, Keller, Dayton; the Sproul and several other mills on Carson river, besides a number of small establishments along Gold canyon, one or two about Virginia City and several along Six-Mile canyon, in the Flowery district. In the next number of these papers something will be said about the Ophir, Gould & Curry and other extensive works put up in 1861-2 at an enormous expenditure of money, but which, after a few years, ceased operations and were finally dismantled, with some remarks upon the causes that lead to these disastrous results.

REAR-ADMIRAL JAMES ALDEN died in this city on Tuesday last. Admiral Alden took part in the Mexican war, and was present at the capture of Vera Cruz and Tabasco. He commanded the *South Carolina* in 1861, the *Richmond* in 1862, and was at the engagement with Forts St. Philip and Jackson, and at the capture of New Orleans. In 1869 he was made Chief of the Bureau of Navigation.

The stagnation of certain manufacturing interests is indicated with terrible distinctness at Newark, N. J., where one-eighth of the population is dependent upon public charity.

One hundred and three deaths from small-pox were reported in London last week, the largest number during the present epidemic, except in the first week of January.

Whip-Making and the Effects of Steady Employment.

Simple as it appears, a first-class linen-plaited whalebone whip is constructed in an exceedingly interesting and ingenious manner, and it requires careful and honest management to uniformly produce a perfect and durable article. The stock for manufacturing must be judiciously chosen and the liquid or sticking material correctly compounded and applied in proper condition. The American Whip Company, of Westfield, Mass., well known in the trade in all American cities, is undoubtedly the largest factory in the world. In no other establishment is so large a variety of whips made in such perfection and great numbers.

Thirty years ago, says Mr. H. J. Bush (one of the leading founders of this company), a knife and plane were all the tools employed by a journeyman whip-maker. Now, we should judge that \$50,000 would not pay for the improved tools and machinery in this single establishment. The most ingenious in construction and operation is the plaiting machinery with its dozens of wheels revolving and carrying different strands of thread in an amazing number of different ways, rapidly forming perfect fitting braid to the varying surface of the whip-stock. One of the latest invented machines plaits the buttons on the stocks more evenly than, and as perfect as, the human hand.

The American Whip Company occupy a large four-story brick building, employing from 40 to 50 men when in full operation. One hundred and fifty dozen or about 2,000 whips can be turned out daily. Although the largest, this factory is only one of many equally well-deserving factories in the vicinity.

Westfield, for more than a quarter of a century, has been noted as being headquarters for whip and cigar-making in the United States. During the past 10 years the town has, from appearances, doubled in wealth if not in population. The braiding of horsehide and buckskin lashes, snaps, and the working of buttons, etc., on whips taken into the industrious homes of the villagers, has given the town a thriftiness rarely enjoyed of late years by their neighbors in other parts of New England. This exemplifies the great benefit to any community of having some light employment for women and children. Although the remuneration may be very low, such employment tells largely in its general results. Some such employment universal in California would produce a wonderful change in the happiness and prosperity of our people.

THE Centennial mine, Nevada county, has paid its first dividend, aggregating \$3,000. The *Foothill Tidings* says of the mine: When it is remembered that the Centennial is a new mine—that only a few months ago the locators of the mine were going round town soliciting parties to take a little stock in it at nominal or "bed-rock" rates, "just to help it on its feet you know,"—and that it has paid its expenses from the word go, and pays now dividend number one, amounting to more than the whole mine was held at a few months ago, we have a realization of why people will continue to put money into these legitimate mining enterprises, even though they do not all pan out as soon and as well as the Centennial. Some of them do and the average will turn out as well as most commercial ventures, if only good judgment followed by good management, go with the investment.

A USEFUL DEVICE.—We received a curious little arrangement this week from C. H. Barrows, of Willimantic, Connecticut, in the shape of a "moustache protector." It is a device to place on the edge of a cup to keep the moustache out of the tea or coffee, and is much better than the ordinary moustache cup. It is self-adjustable, and by means of spring clamps will fit any cup, tumbler, mug or bowl, and is really a useful thing for moustached gentlemen. It may be carried in the vest pocket, being made of very thin metal, nickel plated. The invention is a new one, and is just being introduced for sale.

A CALL has been issued for a meeting of the National Teachers' Association, to be held in Washington on the 1st, 2d and 3d of March. Subjects of interest to the cause of education have been arranged for discussion.

CORRESPONDENCE.

Mines of Beaverhead County, Montana.

[From our Traveling Correspondent.]

The first district encountered going south from Butte City toward Bannack, is that of

Vipond,

Being five miles in length, north and south, and about two miles wide. The general formation is limestone, the mineral belt bounded on the east by quartz, etc., and on the west by porphyry. The direction of lodes in the south end, northerly and southerly, while that of Quartz hill, or northern end, is easterly and westerly. Veins from two to 20 feet thick. Character of ore in the south end, gray copper and much of it plumbiferous, carrying a good percentage in silver, being both free milling and smelting. The ore of the north end is chiefly carbonate of lead and sulphides of silver, with a sufficient amount of the green carbonate of copper to work it, and in consequence a good free milling ore, that runs from \$30 to \$200, or probably making an average of \$60 per ton.

The Mammoth,

(South belt), Messrs. Patton & Branagan proprietors, shaft 40 feet, lode from four to five feet. Thirty-five dollars per ton were realized for 124 tons, sold on dump, unassorted, said to have worked \$62.50 per ton. Ore from the Mewonitoe and the Forest, belonging to the Vipond Bros., was given in as averaging (working process), \$175. The Iridescent (Brown, Leggat & Branagan) produced ore that worked upward of \$80 per ton in silver.

The Argyle,

(South end), owned by Mr. R. D. Leggat, has been worked for the last 18 months, and has a shaft 116 feet in depth, from which levels are now being run, showing as fine a looking body of ore as one could wish to see. The ore has given working tests fully satisfactory to the owner; the figures, for prudential reasons, being at present withheld from the public; suffice it to say that it is one of the most noted and best paying mines of the district, and will probably demand and secure the services of a mill the ensuing season for the working of its ores. Messrs. Dewey, Brubaker and others are reported as having made valuable discoveries on the same vein. The Aurora, North Star, Bismarck and Humboldt, (owned by Prof. Knabe, assayer at the Dexter mill, Butte City,) are developed to a greater or less extent, the first named showing from three to six feet of good milling ore, and all said to look promising.

The Excelsior Lode

(Branagan & Bodge), 80 feet shaft, four feet of quartz, 18 inches of which is high grade, estimated to work \$100 or more to the ton. A Mr. Spur, an old Californian, was met with here, who is fully impressed with the value of his several claims, but requiring some capital to work them. Ore from one of them worked at Reno, Nev., \$122 per ton.

The Monroe Silver Mining Company,

Mr. James Logan Superintendent, have a mine also in Vipond district, and a 15-stamp mill at Dewey's Flat, six miles below the mines. It is provided with a Blake rock breaker (large size), five pans, two of which are of the Purvine pattern, three settlers, three concentrators, (Hendy's), and a large furnace. The mill is large, very substantially built, and conveniently arranged throughout, being planned and constructed by Mr. C. S. Masten, the retiring Superintendent, who is entitled to full credit for its present admirable working condition and efficiency.

The Purvine Pan.

In the absence of Mr. Purvine, who makes his headquarters here, Mr. Masten, who had introduced and used his pan, volunteered the following statement in regard to it, which may be worthy of publication, as it is now attracting considerable attention throughout the Territory. "It is made of wood and combines together all the advantages of the barrel and all other pans, with none of the disadvantages of either. The same ores that have been worked up to 60% in other pans have worked up to as high as 90% in the Purvine pan."

What was said in regard to its mode of construction must necessarily be omitted until the patent is secured.

Copper Sponge and Copper Bars.

Some admirable samples of both were seen here, manufactured (as informed by Mr. Masten) by Mr. Wm. Purvine, inventor of pan and assayer at the mill, and as the facts are of so much interest they will be given as near as possible in his own language. "He has recently worked some of the copper ores of Butte by the Hunt & Douglas process, used by a company in Colorado of which Mr. C. O. Stewart is Superintendent, with very great success, demonstrating that both copper sponge and bar copper can be produced in Butte at very much less cost than copper can be imported, thus adding greatly to the value of the copper ores of Butte and other districts in the Territory, as also to the cheapness of reducing the silver ores."

The Trapper Mines (Burnt Pine P. O.)

Bryant, I think, is the name of the district,

but the above caption has been selected as better known, from the Trapper mine, the first located and opened, being somewhat remarkable both from the quantity and quality of the ores it has produced. Some samples are reported as assaying \$12,000 in silver. It has yielded, according to the best information at hand, about \$40,000 in ore shipped and sold, to say nothing of 2,000 tons on dump, estimated to be worth upwards of \$140,000. The greatest depth attained is 130 feet. The mine is owned by Bryant & Co., who have now a tunnel extended nearly 400 feet, with about 40 feet more to run before tapping the vein at a greater depth.

The Franklin Lode,

Owned by Gild & Co., greatest depth by incline, 65 feet, showing a width of ore at the bottom of 10 feet. One hundred and fifty tons, reduced at the smelting works of Dahler, Armstrong & Co., Glendale, averaged about \$135 per ton, the lowest running \$60 and the highest about \$300 in silver. The general character of ore, carbonate of lead, argentiferous galena and some gray copper ore—the plumbiferous carrying 45% lead. There are 400 tons on the dump, valued at \$75 in silver, taking no account of the lead. The ore at present coming out is of a fine grade, sample assays running \$250 and upwards.

The Elmorlou,

Ford, Lowe & Driscoll, lies in the limestone, the usual formation of the district, with lime on the foot-wall and quartzite on the other; dip south; course east and west. It is opened by shaft 130 feet and a tunnel of 400 feet, for the most part along the vein. The width of ore in some places from one and a half to two feet and widening again to five or six feet. About 500 tons have been shipped and sold, which gave an average as per returns of \$192 in silver, the lead running from 35 to 40%. They have near 300 tons of second-class ore on hand, valued at from \$75 to \$100 and some 60 tons first class for shipping at \$180 in silver. The mine has not only been self-sustaining, but also dividend-paying, a remark that could probably be made truthfully, with some little qualification, about nearly all in the district.

Comparisons, as an old aunt used to say, are "odorous," but odious or not, from what was seen (and by far the best mines were not visited on account of their elevation and the severity of the weather) the remark may be ventured that the districts are few and far between that will show "a hand" with this.

The Cleopatra,

Pease & Co., main shaft, 90 feet; average width of ore vein, six feet, consisting of a solid body of carbonate of lead, giving working assays of 40% in lead and \$50 in silver. The Ariadne, belonging to the same, shafts 55 and 25 feet respectively, average of two feet of ore, mostly sulphide and carbonate of lead. Value of ore from north shaft, \$239.43 silver and 33% lead. The ore body in south shaft is five feet wide, but ore of lower grade thus far, giving about \$20 in silver and 35% lead. The Mark Antony, with about the same amount of developments as last, has a 15-inch vein of ore, chiefly sulphides of lead, running 55% and \$60 in silver.

The True Fissure,

Larwell, Milligan & Co., of Bannack; deepest shaft, 120 feet; ore body, from four to seven feet. Two hundred tons shipped to Salt Lake averaged \$75 in silver. Four hundred tons second class, smelted at Glendale and Argenta, yielded on an average about \$115 per ton. The ore runs in lead from 20 to 50%. Thought to be a very valuable mine.

The Niagara Group.

Owned by Kepler & Co., of Bannack, has three shafts of about 25 feet each. Width of ore on the Niagara proper, three feet; assay value, \$60; 2,788 pounds shipped from one of the group gave returns of \$420 in silver, \$18 in gold and 23% in lead.

The Atlant's,

Armstrong, Atkins & Co. Greatest depth, 140 feet, the ore vein varying from six inches to four feet; character, carbonate and sulphide of lead, and gray copper (fahlore), with a small percentage of carbonate of zinc, carrying also some oxide of iron, and, taken altogether, a good smelting ore. It runs 35% in lead and may be generally considered high grade in silver, some picked samples assaying as high as \$1,500. The mine is systematically worked, and the buildings and fixtures above ground are all arranged for comfort, convenience and effective work. The company own four other claims, the Alta, adjoining, with similar ore; the Cleve, shaft 50 feet and the Avon, 130 feet, running less in lead, with spots of very high grade silver ore, and opening in places to the width of 25 feet. The Hecla has exhibited some of the finest samples found in the district. Work will be prosecuted vigorously the coming spring, and in all probability a mill erected near the mines.

The Sampling and Reduction Works

Of Messrs. Dahler, Armstrong & Co. are situated at Glendale, 10 miles below the mines, where all classes of ore, from free milling to the most rebellious, will be worked, when all the arrangements in progress or in contemplation are fully completed. The furnace, of the cupola form, is built wholly of boiler iron, surrounded by a water jacket. The diameter at the tuyeres is about 30 inches, and it is from 16 to 18 feet high. The flue passes at right angles to a large condensing chamber, having an exit through an underground passage to the stack 80 feet distant. From one to one and a half tons of dust, as rich as the original charge, are collected daily in the condensing chamber. This furnace has

a daily capacity for smelting of about 25 tons, having all the necessary facilities at hand for preparing the ore for further treatment, such as crushers, rolls, screens and jigs. Another furnace had just been completed of the reverberatory form, with condensing chamber built of brick; length, 40 feet by 12 in width. Driving power of works, Leffel's turbine wheel, the water brought by ditch one-half mile in length.

Utopia District,

On Birch creek, has several copper claims, represented to run from 30 to 40%, and one silver claim, a recent location, known as the Franco-American, and located by Longley, Armstrong & Co. It has a three-foot vein of ore, with six inches of high grade, giving assays from \$85 to \$150 in silver and 60% in lead, none as yet being tested by working process.

The Argenta Mines

Contain a larger percentage in lead and a smaller in silver than those of surrounding districts, but the galena ores are utilized and made profitable for fluxing the richer ores from Trapper and other neighboring camps, 50 per cent, being allowed for every unit above 45 per cent. in lead and the full amount for all the silver over \$10 per ton.

There are two smelting furnaces here, one of which was run last year for a few months by Stapleton & Co. with very good results.

The Louis Phillip & Rittenhouse

(Mauldon, Loughridge & Barber), the former showed by means of an open cut a 7-foot vein, rich in lead (66 per cent.), and carrying \$25 in silver. The proportion of silver in the other was higher, the lead running somewhat lower.

The Eaton,

(E. S. Ball), shaft 112 feet, 7 feet from wall to wall, with 42 inches of ore, principally carbonate of lead, averaging 66% per cent. lead and \$22 silver.

Elkhorn District,

Twenty-eight miles west of Bannack, shows many good veins, encased in granite, running principally in silver, with some copper and lead. The Elkhorn, owned by Steele, Graves & Peck, of Bannack, has a shaft of 40 feet, and a 4-foot vein of solid ore, some of high grade, a carload shipped to Salt Lake bringing in the neighborhood of \$150 per ton, silver.

The Storm Lode,

(Steel & Shineberger) has a good large vein, from 4 to 8 feet of similar ore, a lot shipped going about \$140.

The Emerald,

(Mead & Roe), in same direction but 8 miles nearer Bannack, had made a shipment to Utah that yielded upwards of \$100 per ton in silver. It is thought that first-class, selected would run much higher, as it gives assays as high as \$300. About 10 miles north of Bannack promising gold and silver quartz have been discovered at

Bald Mountain.

The formation is limestone and quartzite, and also granite. Mr. A. H. Odell, of Bannack, who has an interest in several silver leads, gives average width at from 2 to 3 feet, and the assays from \$60 to \$400 for silver, the gold quartz running from \$15 to \$50; water and wood in abundance.

The Mines at Bannack—The Del Monte,

Three miles from town (Blue Wing district); fissure, seven feet, and two veins of ore, eight inches each; general character, arsenical and ruby silver. It has yielded to date about \$50,000, and is represented as having paid handsomely. After sinking to the depth of 225 feet, water was encountered and the work was stopped until heavier machinery could be procured. Owned by Messrs. Smith & Sears.

The Czar

(Mr. Clark Smith), has a three-foot fissure in granite, with 12 inches of silver ore, averaging \$100 per ton, selected running as high as \$160 per ton. It is opened by tunnel; the greatest depth from surface, 110 feet; and has paid from the start.

The Huron

(S. Bachelor). Vein varying from a few inches to four or five feet, the ore high grade, but found in pockets. A lot shipped to Swansea brought upwards of \$400 per ton.

The Charley Oak.

(Herr & Ney Bros.) Lode from two to ten feet in limestone, but as yet not well defined, so much of it being barren, the ore being found in chimneys. It gave sample assays as high as \$400 per ton, and a few tons were reported from which about \$100 per ton were realized. It exhibits some rich specimens, and, in view of developments, the prospect may be considered good.

Some Mines of Bannack District.

Mr. Innis is opening a vein somewhat contorted and broken up at the surface and near the border line between the lime and the granite, showing considerable gold quartz, valued at \$20 to \$30 per ton, and other promising indications, that would be considered very flattering in California or Nevada.

The Lookout

Peneluna & Underwood, is giving forth some fine gold quartz, from pockets and small veins, that works from \$30 to \$60. Being near the surface, there is no well defined vein, but has the appearance, in miners' parlance, of a "big blow-out," and indicative of a chimney of ore in a more concentrated form, if followed to a sufficient depth. It matters not whether a vein is well defined or not, so it pays. This mine, with expenditures light, has (within a compar-

atively brief period) produced something upwards of \$10,000 in the gross, handsomely rewarding its owners for their time and labor.

The Dacoto Mine,

Owned and worked by Mr. Phil. Shenon, consists of two claims, opened by three shafts; the greatest depth reached in the lead, 325 feet; and good hoisting works on what is known as claim No. 8. The developments show it to be a contact vein between the lime and the granite, averaging four feet of ore, which pays, in gold, \$50 per ton, some having worked as high as \$65. It is represented as one of the oldest and best paying mines of the district and of the Territory.

Dividend Paying.

In this same vicinity there are four other gold leads, owned and worked by Messrs. Shenon & Co., that have yielded a large amount in the past, and are said to be paying their regular dividends.

The Excelsior,

The most promising, perhaps, of the number, is also a contact vein, with an average of six feet of ore, decomposed and oxidized above water level, changing, as might be expected, below this point to sulphurets of iron. The ore is exceedingly rich, some of it said to yield as high as \$500 per ton, and to average throughout \$100 in gold. Extravagant as these statements may appear, they are deemed wholly reliable, as the mines are not far sale.

This letter closes notes of the mines of Montana. If the reader has carefully perused what has been written (generally conscientiously and guardedly), he must come to the conclusion that no more inviting field is probably presented anywhere in the wide world for the profitable investment of capital; the only drawback, its inaccessibility; its greatest need, a railroad.

A. C. K.

Arizona as a Mining Country.

EDITORS PRESS:—Although the PRESS has many readers in this Territory, few of them take pains to send to the editors such items concerning our mines as would be gladly received and published, yet the remark is frequently made that the PRESS does not have anything in it about our mines, except what it gets out of the *Miner* or the *Citizen*. So, for the purpose of giving some items to the public through your columns, and to fulfill a promise made some months ago, this communication is begun.

As the Southern Pacific railroad approaches the western boundaries of Arizona, and travel hither is made easier, a great deal of interest is manifested in the Territory by mining men in California, Nevada and Oregon, and information of our mineral resources and prospects is sought in every available method, and a few general remarks on that subject will serve as a prelude to statements concerning particular localities, mining districts and mines. The isolated situation of Arizona, erroneous impressions as to the climate, productiveness of the soil, value and extent of the mineral lands, and above all, the Apache war, which was brought to close only two years ago, have all tended to keep the progress of the country back, and, until recently, no reports of the richness of the few mines that were producing bullion caused any desire among outsiders to come here to examine the country and learn for themselves.

The fact is, Arizona is pre-eminently a mining section. There is mineral almost everywhere, productive, valuable mines of gold, silver, copper and lead exist in each of the six counties of the Territory, and large deposits of coal, iron and salt are known of, but remain untouched. The agricultural portion of the country is limited in comparison with the whole area, the valleys of the Colorado, Gila and Salt rivers having the only large bodies of tillable land, but there is enough to raise supplies for a large mining population, and but little chance of a surplus, even at this time, and as the mines are further developed, a good portion of our flour must be brought from Mexico and California.

Grass grows everywhere, but in many sections the scarcity of water prevents stock-raising on a large scale. From Prescott, east, 300 miles to the line of New Mexico, the country is heavily timbered with pine, oak, fir and black walnut, and in the southern portion, below Tucson, the mountains have a heavy growth of the same, but the greater portion of Arizona is destitute of timber suitable for manufacturing into lumber, though sufficient cedar, pinon, mesquit and other scrubby wood is found in nearly all sections for firewood.

The remark is often made, even by the oldest settlers, that if Arizona is not a good mining country it is not worth what the Apache war cost for any other purpose. It is now about 14 years since the excitement caused by the wonderful placer diggings at Antelope Hill and Weaver, 50 miles south from Prescott, drew hundreds of miners into the northern portion of Arizona, and all who explored the country at all were astonished at the discoveries made of quartz veins in all quarters, and of such promising character that many settled down here, determined to look no farther for mining prospects, believing that at most but a year or two could pass away before there would be a rush here to the quartz mines, as there was to Nevada in the days of the Washoe excitement; yet those men

MECHANICAL PROGRESS.

A Crack in the Great Gun.

We have formerly given an outline of the method which the English are employing to make their mammoth cannons. Just on the eve of the completion of the 81-ton gun, a vexatious mishap has occurred which *Iron* says is serious enough, but not thought of sufficient importance to prevent the carrying out of the programme. The holes pierced through the body of the gun, for insertion of the pressure gauges, have been calculated to weaken it considerably, and it should be mentioned, to the credit of the gun, that it has fired 166 rounds, in which it has consumed no less than 23 tons of powder, and discharged 130 tons of projectiles. To this must be added the fact that the charges fired in the later stages of the trials have been much heavier than contemplated when the gun was originally designed, and that the closer confinement of the powder gases obtained by the use of the gas-check has also to some degree added to the work imposed upon the great gun. The authorities, therefore, have regarded, and still regard, with satisfaction, the unimpaired condition of the main structure, while they at the same time admit, as they have invariably done, that the steel tube, or lining of the gun, is its one weak and untrustworthy part. In this steel tube a crack has been discovered. Gutta-percha impressions of the bore have been taken at various stages, and the examination made in this way, preparatory to the renewed trials arranged for this week, revealed evidence of the incipient fracture. It is considered somewhat remarkable, although not surprising, that the 81-ton gun should have followed so closely the example of the original Woolwich infant, the first 35-ton gun, which in a similar manner endured some enormous pressure and then cracked its steel lining; after which mishap it, however, fired many more very heavy rounds, and proved that a defect in the steel tubing was scarcely to be regarded as any very serious detriment to the weapon. English artillerymen, generally speaking, have no faith in steel, in consequence of its brittle nature, but they require a hard, smooth and unyielding surface within the bore, to take the rifling and endure the friction of the projectile; and they have, therefore, reluctantly adopted for this purpose a material, the characteristics of which are the opposite of the tough and elastic wrought-iron coils which compose the body of the gun. The thickness of the steel at the place where the crack has occurred, is about four inches, and it is situated at some distance from the powder chamber, and is at present scarcely perceptible, and of small extent. It is calculated that two or three rounds have been fired since the injury occurred, and that the gun is as fit for work as ever it was, the tubing never being calculated upon as contributing anything to the strength of the barrel. The trial of the gun against the enormous armor-plated target will therefore probably be made, as arranged, at Shoeburyness, before it is retubed.

Design in Steam Boilers.

We find, in the *Indianapolis Mechanical Magazine*, some points in the designing of steam boilers, which, though rather abstract, are worth bearing in mind: It has become a general assertion among writers on the steam boiler that the most important object to be attained in its design and arrangement is thorough combustion of the fuel. This is only partially true, as there are other conditions equally important, among which are *strength, durability, safety, economy and adaptability* to the particular circumstances under which it is to be used. However complete the combustion may be, unless its products can be easily and rapidly transferred to the water, and unless the means for the escape of the steam from the surfaces on which it is generated are easy and direct, the boiler will fail to produce satisfactory results, either in point of durability or economy of fuel.

Strength means the power to sustain the internal pressure to which the boiler may be subjected in ordinary use, and under careful and intelligent management.

To secure *durability* the material must be capable of resisting the chemical action of the minerals contained in the water; and the boiler ought to be designed so as to produce the least strain under the highest state of expansion to which it may be subjected—be so constructed that all the parts will be subjected to an equal expansion, contraction, push, pull and strain, and be intelligently and thoroughly cared for after being put in use. These objects, however, can only be obtained by the aid of a knowledge of the principles of mechanics, the strength and resistance of materials, the laws of expansion and contraction, the action of heat on bodies, etc. The economy of a steam boiler is influenced by the following conditions: Cost and quality of material, design, character of workmanship employed in its construction, space occupied, capability of the material to resist the chemical action of the ingredients contained in the water, the facilities it affords for the transmission of the heat from the furnace to the water, etc. The *safety* of any structure depends on the designer's knowledge of the principles of mechanics, the resistance of materials and the action of bodies as influenced by the elements to which they are exposed; and in the case of steam boilers the safety depends upon the judgment of the de-

signer, the quality of the material, the character of the workmanship, and the skill employed in the management. Safety is said to be incompatible with economy, but this is undoubtedly a mistake, as intelligent economy includes permanence, and seeks durability.

Adaptability to the peculiar purposes for which they are to be used, is one of the first objects to be sought for in the design and construction of any class of machines, vessels or instruments, and it is undoubtedly this that gives rise to the great variety of steam boilers in use at the present day, which are, with very few exceptions, the results of thought, study, investigation and experiment.

Machines in New South Wales.

In the months of April and May an exhibition will be held at Sydney, New South Wales. There is in this colony a particular need of labor-saving machinery and inventions. Manufacturers of such may find it profitable to co-operate in the exhibition. The following extract of a letter from the Executive Commissioner of the colony at the Centennial offers some valuable suggestions as to the kinds of machines required: The greater portion of the best pastoral lands of Australia are wholly without surface water, and generally when wells are sunk they only reach salt water. Therefore, the great requirements are apparatus for sinking through the saline stratum to the fresh water which probably lies below; and especially appliances for excavating tanks or reservoirs, into which the rainfall may be led from the plains. The most effective pumps for use on land or in ships are desirable objects of exhibition. So, also, are the best agricultural machinery and implements, being strong and simple in construction. Timber saving machinery always finds a sale, and, if adapted to felling standing trees, and to cut them into lengths when on the ground, so much the better. This opportunity of bringing railway appliances to the notice of the Australian governments, which own nearly all the railroads, should not be neglected. Such a display would undoubtedly attract the principal civil engineers from all the colonies, and many prejudices would be removed. There are very many articles in the Centennial buildings which would, when known, be introduced into Australia advantageously to the makers. I will mention a few only: Brickmaking machines, if cheap and strong; small cheap planers and matchers; scroll saws; the latest improved wood-working machinery; any small, ingenious household goods of the latest patents; spring wagons of best construction; lightning cross-cut saws; samples of furnishing goods, etc. There are very few articles subject to duty in New South Wales, but any reasonable quantity of dutiable goods for exhibition will be admitted free of the custom house, which will have no control over anything which enters our exhibition buildings. Everything for the exhibition should be addressed to Jules Joubert, Esq., Secretary of the New South Wales Agricultural Society, Sydney, so that it may be taken free of expense to the exhibition building, and otherwise cared for.

Starting the Drill.

Prof. Sweet makes the following note in the *Polytechnic Review*: In the ordinary practice of drilling it is customary to locate the center of the hole and make a small indentation with a center punch; then to strike a circle with the compass the size of the hole to be drilled, and to firmly fix the location in case the circle gets obliterated, four center punch marks are made on the four sides of the circle, so that in starting the drill, if it does not start truly central, as they seldom do, the four marks will indicate the direction in which it is out of its proper place. It is also customary, when starting the drill, to examine carefully to see that it is starting true, or if it draws to one side to chip out with a round nose chipping chisel on that side, so as to bring the drill back central. I do not think this the best way—at least, the best for only those who have worked that way for years. When a man has followed one practice, and has become an expert at it, then a new way must be a very superior one to make it to his interest to change; but with you who have two ways put before you, neither of which you are familiar with, then I think the plan of drilling a small hole as quick and more certain of success. If the indentation of the center punch be as large as the small drill, then the small drill cannot be started anywhere except in the right place; and if the small drill be about as large as the thickness of the point of the large drill, then a large drill hole will follow the small one to a certainty, if there are no flaws or blow-holes in the metal, and they are hard to fight against in any case. The use of the small drill, and then the larger one, calls for a change of speed in the machine. To overcome this objection, I have thought of making a drill chuck to fit upon the same spindle, that shall have within itself a speed gear which will give the drill a speed eight or ten times faster than the speed of the spindle of the machine; then by simply changing chucks the small drill will have the proper speed when the machine is set at the proper speed for the large one. The nature of the mechanism to accomplish this is only a planetary gear, the same as the back gear of our lathe made on a small scale. Another improvement, that can be made on drilling machines, is some better method of securing chucks—the present method is to slow—some modification of the bayonet fastening is the thing.

SCIENTIFIC PROGRESS.

The Laws of Taste and Smell.

Dr. Hughlings Jackson, whose name has long been familiar as that of one of the first neurologists of the age, has just published a series of observations as to the relative functions of the olfactory and gustatory nerves, which are summarized by the *Phrenological Journal*: To understand how complex the sensation of taste, as generally spoken of, really is, it must be remembered, that the membranes of the mouth and the surface of the tongue are abundantly supplied with tact-buds, or papillae of ordinary feeling; so that what is styled taste is always accompanied by a perception of form and consistence, and of heat or cold. Sliminess, for example, is a perception of the tact-buds, not of the taste-buds. Lastly, the distribution of the olfactory nerve is so intimately connected with that of the nerve of gustation that the two usually act in unison. Thus what is generally, though inaccurately, styled taste is a triple sensation, involving the simultaneous impression of nerves of feeling, smell, and taste. It becomes important, therefore, to discriminate, since the fifth pair, the glosso-pharyngeal, and the olfactory nerves are all involved in the function of taste, and an impairment of the function, in the ordinary acceptance of the term, may imply lesion of either. In point of fact, as a general rule, when patients complain of impairment of the sense of taste, it will be found on experiment that the olfactory nerve is the part especially affected, and that there is really no loss of function in the fifth pair. A very simple experiment will settle this question. Drop a little essence of peppermint on a lump of loaf sugar, and place it upon the patient's tongue. The tact-buds will respond with a sensation of heat, and the taste-buds will perceive the proper taste of the sugar, if the function of the fifth pair is undisturbed; while, if there is defective olfaction, what is styled the taste of peppermint will be absent. Conversely, if the latter is present, and it is the sugar that remains unperceived, then the taste-buds have lost their function, and the olfactory nerve is not the seat of the lesion. Camphor in solution, dropped on sugar, is also a good test. The point is, that neither peppermint nor camphor have any proper taste, but are in reality smelled. Blood is said to have a salty taste; but in reality it is not the albuminous constituents of the blood, but several salts, held in solution in them, that are tasted. The remainder of the impression is one of flavor and of consistency, apprehended by the nerves of feeling and the olfactory filaments. And this brings on the distinction in function between the olfactory nerves and the filaments of gustation, as founded in nature. It is thus: Crystalline bodies, soluble in water, or in the secretion of the salivary glands, are tasted; colloid bodies, oxidizable in air, and susceptible of diffusion, are smelled. Thus sugar, salt, etc., are tasted, and have no effect whatever on the olfactory nerves; while, with colloid compounds, the sensation is due to an aroma that is apprehended by smell. With mixed bodies, colloid but holding crystalline elements in solution, such as animal and vegetable tissues, the so-called sensation of taste is always a mixed one. It would be a mistake to suppose that, because an aromatic body has a sweetish taste, the aroma and the taste are due to the same constituents. Carbolic acid has a sweetish taste, but aroma proceeds from unseparated impurities, and the more refined the acid, the less it impresses the olfactory nerves. The distinction, then, between smellable and tasteable bodies, is purely one of solubility in water or in air; and the sense of taste may be as readily destroyed by loss of function in the salivary glands as by loss of function in the taste-buds themselves. It will be seen, therefore, that to make a correct diagnosis in a case of this kind, involves an exceedingly careful and exact analysis of all the functions represented by the mouth and nose.

The Wheeler Surveys.

A dispatch from Washington gives the following information:

The annual report of the surveys west of the one hundredth meridian, under the direction of Lieutenant Wheeler, United States Corps of Engineers, is now about ready to be issued. It will exhibit many interesting facts regarding the topography and resources of the regions examined in Colorado, New Mexico and California during the last fiscal year, under special instructions from the War Department. An examination was made to ascertain whether the waters of the Great Colorado River of the West could be diverted to the adjoining plains for purposes of irrigation. The report thereon is accompanied with illustrations and regulated data, showing the problem to be difficult if not impracticable. Special investigations have been inaugurated with a view to distinctively delineating in colors upon the atlas and maps of the survey the irrigable, grazing, mineral and mountain sections of the whole region hitherto explored by the Wheeler expedition, covering, since the year 1869, nearly 400,000 square miles. These expeditions have been sent out by the War Department principally for the purpose of gathering topographical data for the mapping of the country, and incidentally to report on the mineral, agricultural and other resources of the re-

gion west of the one hundredth meridian, and its geology, climate, etc. Maps of a large portion of the area have already been published. The matured results of the survey are to be published in seven quarto volumes. Two of these, viz., geology and zoology, have already appeared; the third, paleontology, is nearly ready for distribution, and the remainder well advanced. Topographical and geological atlas sheets will be issued from time to time. There will be also issued a monograph upon the routes of communication, showing distances between elevations, wood, water, grass, etc. This information is much sought for by parties contemplating the locating of colonies, the transfer of large herds to grazing grounds, etc. The appropriations for this work last year, although limited in amount and not available until late in the summer, have afforded gratifying results, several field parties continuing their labors up to December, and returning to headquarters in Washington well laden with data to be elaborated and submitted directly to Government and incidentally to the public. If Congress makes adequate appropriations during the present session, parties will be put in the field early in the coming spring, as skilled assistants, instruments and outfits are all at hand ready for camping at any time.

The English Believe in the Sea Serpent.

The *London Spectator* gives full credit to the last reported observation of the sea serpent. Its appearance coincides with what is now agreed upon, that it must be of a Saurian character, like the monsters of geologic periods. The *Spectator* says, "In the Straits of Malacca the sea-monster, so repeatedly seen and so repeatedly declared to be mythical, appears at last to have been carefully observed by competent witnesses. The creature was seen by the passengers and crew of the ship *Nestor*, on her voyage to Shanghai; and on her arrival at Shanghai the master of the ship, Mr. John Keiller Webster, and the surgeon, Mr. James Anderson, made a statutory declaration of what they had seen before a magistrate, as a mode, we suppose, of formally attesting that they spoke in good faith. The creature (which resembled a huge salamander, only that instead of being about six or eight inches long, these dimensions must be multiplied by at least 75 or 100, the body being from 45 to 50 feet in length, the head 12 feet, and the tail, it is said, no less than 150 feet) was first seen at half past ten o'clock on the 11th of September, 15 miles northwest of the North Sand Lighthouse, in the Straits of Malacca. The weather was fine, the sea smooth, and the air perfectly clear. The Chinese on deck were terribly alarmed and set up a howl. The whole watch and three saloon passengers saw the creature clearly and observed its movements. It traveled for a long time about as fast as the steamer, appearing to paddle itself by the help of 'an undulatory motion of its tail in a vertical plane.' The body and tail were marked as those of the salamander are marked—with alternate bands, black and pale yellow in color. 'The head was immediately connected with the body, without any indication of a neck.' Both witnesses state positively that the only resemblance was to some creature of the frog or newt kind, while one of them (the surgeon) says the longer he observed it the more he was struck with its resemblance to a gigantic salamander. Its back was oval in form. No eyes or fins were seen and it did not blow or spout in the manner of a whale. The greater part of its head was never seen, being beneath the surface. Probably the creature is of a race which survives from that very different world in which creatures of gigantic size seem to have been so much commoner than now. There appears to be no manner of reason for doubting the very express evidence so succinctly and soberly given."

The Distance of the Sun.

If some celestial railway could be imagined, the journey to the sun, even if our trains ran 60 miles an hour, day and night and without a stop, would require over 175 years. Sensation, even, would not travel so far in a human lifetime. To borrow the curious illustration of Prof. Mendenhall, if we could imagine an infant with an arm long enough to enable him to touch the sun and burn himself, he would die of old age before the pain could reach him. According to the experiments of Helmholtz and others, a nervous shock is communicated only at the rate of about 100 feet per second, or 1,637 miles a day, and would need more than 150 years to complete the journey. Sound would do it in about 14 years if it could be transmitted, and a cannon-ball in about nine, if it were to move uniformly with the same speed as when it left the muzzle of the gun. If the earth could be suddenly stopped in her orbit, and allowed to fall unobstructed toward the sun under the accelerating influence of his attraction, she would reach the central fire in about four months. I have said if she could be stopped, but such is the compass of her orbit that, to make its circuit in a year, she has to move nearly 19 miles a second, or more than 50 times faster than the swiftest rifle ball; and in moving 20 miles she deviates from perfect straightness by less than one-eighth of an inch. And yet, over all the circumference of this tremendous orbit, the sun exercises his dominion, and every pulsation of his surface receives its response from the subject earth.—Prof. C. A. Young, in *Popular Science Monthly* for February.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR.

TALIMAN.—*Amador Ledger*, Feb. 3: We have been shown specimens of the rock from the recently discovered vein of quartz in this mine. It shows large quantities of gold bearing sulphurets, and also free gold scattered plentifully through it. Good judges pronounce it the finest looking ore ever seen in Amador county. The richest part of the ledge is about 20 inches wide, with good paying rock on either side.

EAST KEYSTONE.—We are informed that a fine ledge of quartz was struck in this claim last week.

GREEN POINT.—The 10-stamp mill will be started to-day (Saturday). There appears to be any quantity of rock of fair grade. Sanfrancisco persons estimate the ore at \$15 or \$20 per ton, but the owners will be satisfied if it averages \$8 or \$10 in gold. There is some talk among the shareholders of increasing the capacity of the mill to 20 stamps, should the actual trial of the ore prove satisfactory.

THE MECHANICS mining company have leased the old Downs mill on Sutter creek. It is intended to put in 20 stamps and start running without delay. All the shares thrown upon the market for obtaining working capital have been disposed of.

PROSPECTING.—A large number of persons are still prospecting for quartz between Amador City and Plymouth. Some Italianes struck a rich ledge on Wednesday, the particulars of which have not reached us. It is safe to assert that the stimulus imparted to prospecting operations in the region indicated can scarcely fail to lead to the development of permanent mining operations.

THE 80 STAMPS of the Phoenix mill keep up their ceaseless beating, grinding out the usual quantity of bullion. We visited the mine during the week. The mine is looking as well as ever.

CALAVERAS.

TIGER.—*Calaveras Chronicle*, Feb. 3: We understand that the new mill at the Tiger mine, Rich Gulch flat, works admirably. The mine is kept constantly employed and the mine is looking first rate.

UREKA COUNTRY DOTS.—Work has been recommenced in the Hall and Lacey tunnel, near West Point, the object being to tap a quartz ledge which cannot be worked through a shaft on account of the prevalence of water. The tunnel is in over 300 feet and is expected to cut across the vein at a short distance further. Excellent rock continues to be taken from the tunnel. The breaks on Clark's ditch, caused by the late rains, have been repaired and miners are busy throughout the section of country covered by the canal.

INYO.

LARGE PURCHASE.—*Coso Mining News*, Feb. 3: Mr. H. W. Fortune has succeeded in purchasing for his company the Hidalgo mine and the Portals furnace site, for the Santa Rita mining company, of which he is one of the principal owners. The mine is considered one of the best in the district, there being now on the dumps several hundred tons of most excellent ore. The furnace property is good, so far as goes, but is not of sufficient capacity, and the machinery for another one has been shipped. A contract has been let for running a tunnel for exploiting the mine and for convenient facilities. We understand that the most energetic operations are to be inaugurated at once, Mr. Fortune having gone below to consult with his co-owners relative thereto.

KERN.

HOT SPRINGS.—*Cor. Courier-Californian*, Feb. 1: Dr. Blatchley, the mining engineer of the Bull Run mines, passed up to-day. Operations are to commence there in earnest. The prospects of that camp improve constantly, in spite of the general dullness in mining affairs. The S. & G. company are preparing to erect a mill on Erskine creek at once. There is every encouragement in the showing made so far, and Erskine creek will yet secure the name promised it so many years ago. Some extraordinary rich ore has been struck in the Big Blue, but the working party was driven out by water. The new and powerful pump, however, will dry it out in a few days. The placer mine at Keyville is still going on, paying well, with good prospect of increase.

NEVADA.

ROUGH AND READY.—*Grass Valley Union*, Feb. 4: Good progress continues to be made on the mine. The machinery for the hoisting works is about in running order, so that sinking below the first level can be commenced. Work is on the first or tunnel level being done steadily. A good strong ledge shows all the way, and the rock is of good quality. In about two weeks more the mill will be ready to start up.

DIVIDEND.—The Trustees of the Idaho company held a meeting yesterday and declared a dividend of \$7.50 per share of capital stock of the company. The dividend is payable immediately.

ALASKA.—This mine is proving itself to be worth something as a gold producer. A crushing of ore was made last week at the Omaha mill, and the result was very cheering. Thirty-five loads of rock, in which there were considerable "waste" matter, was put through the mill and yielded about \$50 per load in free gold—not counting the sulphurets.

NEVADA.—*Nevada Transcript*, Feb. 3: The pump at the New England mine has drained the ground adjacent to the hoisting works so that a company is able to prospect a ledge running parallel, and a short distance east of the New England. Gold flat has a large number of small veins through it, most of which prospect well on the surface, but the ground has always been so full of water that but little work could be done on them.

THE GOLD RICH mine has been still sinking their incline. It was intended to go down 200 feet before any more drifts would be run. They have gone between 130 and 140 feet now.

NEW ENGLAND MINE.—We visited the above mine on Saturday last and found everything working admirably. Rock is being taken out of the ledge east of the shaft, and the work of drifting west to strike the main ledge is progressing as fast as the nature of the ground will permit of. There was about 40 tons of ore on the dump, and it is considered by all who have examined it to be first-class. It is filled with sulphurets and prospects well. Fifty tons of it will be crushed at Keith's mill, in this city, several tons having already been drawn, and crushing on it commenced. No one estimates the yield at less than \$25.

THE PITTSBURGH mine has the softest thing on the wood and water question of any mine in the country. The V flume runs directly over one corner of the mill and all the wood used can be dumped directly from it and supplied for \$3.50 per cord. Fresh pure water can also be obtained for the boilers from the flume by simply attaching a pipe.

PLAOR.

BLAST.—*Dutch Flat Forum*, Feb. 1: On Friday a charge of 2,000 pounds of Giant powder, No. 3, was exploded in the Baker claim, doing good execution, and on Saturday work was turned on and washing commenced. The explosive used is new article in the market, and is known as Judson or Giant No. 3, and is said to be three times as strong as the common black powder.

THE LIBERTY HILL company are now washing with all the water they can use to advantage. With a large force of men, assisted by powder and a derrick, they are now making a splendid showing.

THE DUTCH FLAT, owned by B. Huysink, of Dutch Flat, situated north and adjoining the Liberty Hill mine; it has a width of 300 feet by 1,200 feet along the channel. The gravel was tapped in this mine through a tunnel 600 feet in length, run from Liberty Hill ravine. They have

already run several prospecting drifts, we understand, with satisfactory results, the gravel in places being very rich.

LITTLE YORK.—The Empire and Christmas Hill mines are both washing, with a full head of water. Being fitted up in fine style Mr. Morgan, the superintendent, who is an experienced miner, expects to make a splendid showing this season out of the different claims under his supervision, which includes the Liberty Hill mine.

MINING AT FOOL'S HILL.—The mines at this place are owned and carried on under the supervision of McManus & Preston, and are situated on the north bank of Bear river, immediately below Fool's hill. They embrace a deep channel, 75 feet in width and 900 feet in length, and sink the bedrock has never been reached. The run rock on both sides of the channel scale worked several years ago by other parties, through tunnels, and was very rich. The present owners tried the deep channel through a shaft, but after reaching a depth of 50 feet below where the ground had been worked, they were forced to abandon it on account of the large increase of water. They are now running an incline at an angle of 45 degrees, and are sinking 50 feet. The bedrock works on Wilcox pass a force pump are run by a horse wheel, all of the machinery working to a chain. The gravel through which they are now passing only carries sufficient gold to pay for hydraulic, but they expect to strike a bonanza on reaching the bedrock, as the gold found on both sides of the channel and on Fool's hill was very coarse and lying on the bedrock.

THE YUKON.—There has been a great deal of work done in the Opal claim since our last mention. The loose top ground has all been washed off and a shaft raised from the bedrock tunnel, through which they have been washing for some time, receiving their supply of water from the ditch of the Green Valley Co. Hayden Hill Co. is being worked under the supervision of James Ross, one of the owners. They have been busily engaged for the past several months in getting in shape, during which time there have been several necessary improvements added to the works connected with it. A large head of water is now used, and the work of removing the gravel is progressing rapidly. Novey Co. have their cement mill built and in readiness to commence crushing, the tunnel is also completed and the work of raising a stopes will be finished in a few days, when the mill will be started up and kept crushing what is said to be very rich cement.

PLUMAS.

RICH QUARTZ.—*Plumas National*, Feb. 3: Some developments recently made on a quartz ledge near the head of Rich creek, about 10 miles from the mouth of the river, have brought to light some of the richest quartz ever seen in Plumas county. We are credibly informed that specimens have been taken out which, when the rock is broken up, hang together by the gold, and that tons now in sight will pay at the rate of \$100 to the ton. The ledge has been claimed for many years, but little or no work has hitherto been done on it, and until lately it was not considered a rich ledge. Operations were commenced in 1875, and probably hundreds of such chances await the hand of the lucky prospector.

ITEMS.—The Eureka mine is paying largely, and provides right to the title of the best quartz mine in the State. Tommy Ivy and Tommy Taylor are opening a new claim near Taylor creek, with good prospects. The Gold Stripe mine is looking better every day. Wolf creek is bound to be a rich mine. The Marysville land office, against the Plumas Eureka Co.'s claim to the Hooper Extension of the Eureka ledge.

SIERRA.

WATER.—*Mountain Messenger*, Feb. 3: The recent storm made some water for the Bald Mountain, so that they were enabled to commence washing on the dumps. **GOOD PAY.**—Peter Kelley has been getting good pay in a tunnel under the street, near Bosch's brewery. In one forenoon he and his partner took out \$50, which is very good for these desperate days.

PROSPECTING.—Several others have been endeavoring to sink a shaft on the hill north of town and above the Garibaldi ranch. They got down only 40 feet on account of water. We understand they intend running a tunnel, being satisfied that they can strike the channel, if one exists, at the proper angle, from the data gained in the shaft.

EXPERIMENT.—The Brush Creek quartz mine, at the Mountain base, has been at last being worked. It was prospecting by Jos. Middlemiss, of San Francisco, J. P. Brown, of Camptonville, and D. T. Cole, of Sierra county. Rich rock has been discovered directly under the old works and in other places where these gentlemen figured it must be. Mr. Middlemiss is entitled to much credit for the ability and success with which he has induced capitalists below to interest themselves in this matter, and we trust that both he and his associates will be rewarded with handsome dividends, which the rich quartz specimens extracted fully warrant. As soon as practicable their mill will be crushing rock.

SISKIYOU.

THE EMPIRE QUARTZ COMPANY.—*Yreka Journal*, Feb. 3: The members of this company held a meeting during the week for the purpose of hearing a report of how things were going on at the mine and deciding upon how they should proceed. As we stated a few weeks ago, the company have most excellent prospects. They have just made the connection between the shaft and the tunnel, the shaft being about 50 feet deep and the tunnel in between 100 and 120 feet. The ledge is full five feet in width, with good walls, and all the quartz taken out prospects evenly and regular, which fact we hold to be one of the best indications of a good permanent ledge. The company have determined to push the tunnel ahead a little further, and then sink an incline on the ledge again to prospect it still further down. If at the depth of 50 feet more the ledge proves to be what it now promises, the company will not doubt increase their force of miners and proceed to put up a mill. We sincerely hope the enterprising owners of this mine will reap a golden harvest for their pluck and enterprise.

SONOMA.

GREAT EASTERN.—*Sonoma Democrat*, Feb. 3: The Great Eastern mine near Guerneville is proving to be a mine of considerable value. We were informed by the Superintendent, D. Haskins, that the yield has been about 100 flasks per month for some time back and that it could be increased with a larger furnace. After three years' work the mine continues to improve and those who have given the subject close attention have come to the conclusion that under the management of the present owners, the mine will be a large deposit of this class of ore below. The smaller veins lead to breasts of ore varying in richness. The average is about two per cent. Forty men are at work and the mine is paying the owners and lessees.

Nevada.

WASHOE DISTRICT.

CON. VIRGINIA.—*Gold Hill News*, Feb. 7: Daily yield, 235 tons of ore, keeping the Consolidated mill steadily running. The yield of bullion for the month past will nearly reach \$100,000, which will considerably more than pay the current expenses. There is little or no change in any of the ore-producing sections of the mine. The drift running south from the deep winze just north of the California line on the 1650-ft level is being pushed ahead as fast as the hard character of the ledge will permit. The ore in the face of this drift is still of a fine quality, but the heat is great and the progress necessarily very slow. The west drift from the C. & C. shaft on the 1650-ft level is steadily advancing, the face in very favorable ground. The character of the ore and the formation of the vein at this point is equal if not superior in richness to any level yet opened. The progress, however, in the development, must necessarily be slow on account of the intense heat and bad air, until a connection is completed with the

north winze. There is nearly 100 feet of solid ledge to penetrate before this drift and the one running south from the winze can make a connection. On the 1500-ft level the enlargement of the drifts and air connections is about completed.

SILVER HILL.—Sinking the main incline is now being pressed steadily forward at the rate of 124 feet per week. The rock in the bottom is quite hard and the flow of water somewhat less. The east cross-cut on the 650-ft level is still advancing toward the ledge, with favorable indications of soon reaching it. The face of the northwest drift on the 444-ft level, running to connect with the Justice mine, is in very hard blasting rock, and is advancing at the rate of three feet per day. According to the survey this drift now only lacks 35 to 40 feet of connecting with the Justice. A drift has been sent down a prospect hole to meet the drift on the 444-ft level, so that the connection will soon be completed.

GOLD & CARRY.—The shafts and water tanks in the main shaft are all completed, and the lowering of the pumps and pump-bobs into place has commenced. The shaft and works have not been in as good working shape for the past three years as at this time. In fact, the entire mine is now in better condition than it was a few years' work than it ever was in the past. On the 1700-ft level the south drift is being advanced rapidly to connect with the Savage combination winze on the south line of the mine. The east drift on the 1700-ft level is also being driven forward to reach the clay body in which the diamond drills in use some weeks since stuck fast. The winze below the shaft is being repaired and put in good working condition preparatory to a more thorough prospecting of the 1800-ft level.

CALIFORNIA.—Daily yield, 550 tons of ore, keeping the mills all steadily running. The ore breasts on the 1400, 1500 and 1600-ft levels are all looking splendidly and yielding good ore. The bullion yield for the month of January will not fall much short of \$1,000,000. This income is the result of the regular dividend of \$1,000,000 with a considerable surplus to carry over to the February account. The south drift on the 1600-ft level is steadily advancing toward the north winze, the face still in good ore. This drift has yet 30 or 35 feet to run to connect with the winze. Sinking the C. & C. shaft has been stopped for the present, on account of the need of all the compressed air obtainable in the west drift on the 1650-ft level. The mine is now in a brighter or more prosperous look than at the present time.

LADY BRYAN.—As soon as the setting of the boiler is completed the powerful new pumping engine will be started up, draining the water from the mine. The connections are all made, ready for starting up. The water is only about 350 feet deep in the shaft, but it will take some little time to drain the mine to that depth.

IMPERIAL CON.—The north and south drifts from the bottom of the north winze on the 2135-ft level are each steadily advancing in very favorable ground. The north drift from the bottom of the south winze on the same level is also making good progress. The same may be said of the two east cross-cuts on the 2000-ft level, which show no important changes during the week.

MEXICAN.—The west drift on the 1465-ft level has penetrated the ore vein to very near the west wall of the ledge, cutting some rich spots of ore, but not developing any large or permanent bodies. The north drift on that level is running to connect with the winze below the 1300-ft level is making good progress and is finding some very good indications of ore. The east cross-cut from the north drift on the 1000-ft level is nearly across the vein without finding any large body of pay ore. The prospects, however, developed by this drift are excellent. The north drift on the 1700-ft level is steadily advancing along the west wall of the vein, the face in very favorable vein matter, carrying some streaks of good ore.

BULLION.—The north and south drifts on the 1500-ft level are each showing a fine character of ore-bearing quartz, and have the appearance of being on the top of a fine mineral vein. During the first part of the week the east drift on the 1600-ft level tapped a strong flow of water, which has since been stopped and all work at that point until the water is drained. This flow of water is carried down through the winze to the 1700-ft level, and thence to the Imperial and Yellow Jacket shafts, from which it is taken to the surface.

LEVATHAN.—After extending the main north drift at the 600-ft level nearly 60 feet, following the foot wall of the ore vein, a cross-cut is now being made to the east. This shows a width of about 15 feet of ore, some streaks of which give high assays. It shows constant improvement as the drift is extended.

JULIA.—The south drift on the ore vein on the 1800-ft level is being pushed vigorously forward, the face still in fine quartz and low grade ore. An east cross-cut from this drift has been started 100 feet south of cross-cut No. 1, the face of which is showing a highly improved character of quartz, the assays reaching from \$14 to \$18 per ton.

YELLOW JACKET.—Sinking the new shaft is making splendid progress. There is still a high flow of water at bottom. It is now down 450 feet. On the 2040-ft level the south cross-cut to the eastward has penetrated 40 feet of ground which carries seams of good ore.

MINT.—Opening the station at the 1400-ft level is making the best of progress. As soon as that is finished the shaft will be sunk 25 feet deeper in order to have a pump room for a flow of water, should any be encountered. Then a new ore will be recorded in the history of the mine, and the 1,100 feet of virgin unprospected ledge of the company, stretching a distance of 1,200 feet north and south, will be cross-cut and prospected.

SOUTHERN CONSTRUCTION.—Owing to the very encouraging developments at the 300-ft level, Superintendent Lennon is engaged in cutting out a tank station to catch the flow of water from the shaft, preparatory to sinking the shaft deeper for a new level.

NORTH CON. VIRGINIA.—The putting in of the pumps at the 1150-ft level has been completed and sinking the shaft resumed. Bottom of shaft in very favorable ground and the flow of water light.

SIERRA NEVADA.—The flow of water at the bottom of the main shaft on the 1700-ft level is gradually subsiding. The face of the north drift on the 1700-ft level is still showing a very encouraging character of quartz and low grade ore.

SAVAGE.—Pumps are steadily at work and water is being again gradually lowered. It is now reduced several feet below the 1000-ft station, and is steadily on the increase.

CHOLLAR POROSI.—The main incline is now down 1,790 feet. Sinking the combination shaft is also making the best of headway. Daily yield, 100 tons of ore, the assay value of which is \$29.50.

PROSPECT.—Face of main west drift at the 400-ft level in hard ledge porphyry, with streaks of quartz and clay.

BEST & BELCHER.—The north cross-cut on the 1700-ft level has been started up and is steadily advancing eastward, the face in porphyry mixed with ledge matter.

UNION CON.—The ore prospects in the bottom of the winze below the 1800-ft level are improving daily. The ore and quartz in the face of the north drift on the same level is also showing well.

NORTH CARSON.—At the 500-ft level drifting is pushing ahead lively, with good ore indications.

OVERMAN.—A cross-cut has been started in the ore vein on the 1900-ft level south of the shaft. The upraise on the streaks of ore found in that portion of the mine prove that they give out in ascending, and that they grow wider and richer in descending, so that the appearances are that only the top of the ore has yet been reached by any of the drifts on that level. This is, without doubt, an entire body. The winze being sunk on the ore vein north of the main shaft, the steady improvement as it descends toward the 1800-ft level. The east drift on the 1300-ft level is being advanced cautiously toward the ore vein, as it is not the intention to tap the water at that point if it can be avoided. The east drift on the 1400-ft level is being forwarded with all possible speed in order to drain the water from the vein and thus permit a steady prospecting of the 1300-ft level while the water is draining.

LADY WASHINGTON.—The bottom of the winze being sunk on the ore vein below the north drift on the 850-ft level is still in vein matter of a fine character. The face of the main north drift on the same level is almost solid

quartz of an excellent character, showing a steady increase in assay value as the drift progresses to the north-west toward the Overman. The prospects for finding a paying body of ore in that portion of the mine are daily growing better.

BALTIMORE AND AMERICAN FLAT.—A considerable flow of water was encountered at the bottom of the north winze below the 1650-ft level during the first part of the week. This water is being drained by a small pump run by compressed air. The ore and quartz at the bottom of this winze is showing much more favorable than for some time past.

JUSTICE.—Daily yield, 350 tons of ore, keeping the mills all running up their full crushing capacities. The ore breasts on the 400, 600, 700 and 800-ft levels are looking well and continue the usual yield of milling ore. The water is drained from the face of the southwest drift on the 1000-ft level, and preparations are being made to resume work in the face.

OPINION.—Daily yield, 15 tons of ore, the assay value of which is \$36 per ton. The main incline is now down 35 feet below the 1800-ft station.

BECHER.—Sinking the drain shaft is making good headway. Sinking the main incline is also making fair progress.

HALE & NORCROSS.—The pumps are kept steadily running and are gradually drawing the water from the shaft below the 1900-ft level. It is now reduced 25 feet below that point. The connecting drift with the Savage on the 1000-ft level is very badly caved, the drift being closed and the work of opening it very difficult.

DOWN.—The main incline has reached the 2000-ft level, and as soon as sufficient pump room is obtained the opening of a working station at that point will be commenced.

HOMERTRAD.—The new machinery will soon be on the ground, and a largely increased force of laborers employed in the prosecution of the work.

ASOK & GLASGOW.—The face of the north drift on the 400-ft level is still showing favorable ore and ledge matter.

KOSUTH.—The west cross-cut on the 600-ft level is steadily advancing, with more and more favorable prospects of soon reaching the main ledge.

DAYTON.—The ore prospects in the face of the north drift on the 700-ft level are steadily on the increase.

FLORIDA.—A new pump lift is to be put in at the 780-ft level in a day or two more.

SECOR.—The flow of water is considerable, but is easily handled by the pumps.

TROJAN.—Sinking the winze on the ore vein below the 300-ft level is making good progress, showing a steady continuance downward of the ore body.

NEW YORK.—The completion of the third compartment of the shaft for the pump is being pushed forward as fast as possible.

BUCKLE.—The extraction of ore from the stopes on the 350-ft level north is going steadily forward. It is being crushed at the Hope mill as fast as it is taken out.

GALENA DISTRICT.

PROSPECTS.—*Silver Star*, Feb. 3: McBeth and Melander are working the Buena Vista, and have struck very good galena ore in the shaft, which is now 225 feet deep. They are also working on the Little Giant, located on what is known as the Trinity ledge, and are taking out galena ore rich in silver. The prospects of this being a paying mine are very flattering, and it looks as if McBeth was about to make another raise in mines. The White & Shiloh Co. have resumed work and men and machinery are being sent to connect the shafts of both mines by a drift for ventilating purposes, so as to further develop both locations. The company is now making preparations to build furnaces for the purpose of reducing the ore into bullion on the ground. This will give others who have ore in the vicinity an opportunity to dispose of it or have it reduced at home. The company have a Krom concentrator on their mines, but as it is not of sufficient capacity, Times have been dull in the camp, but they are brightening up a little and Galena will soon be on a sound basis.

Arizona.

THE MINES.—*Arizona Enterprise*, Jan. 21: There is not much that is new in mining matters in Yavapai county since our last. The miners in the several districts are busily at work, and evince an energetic disposition to develop their mines. There seems to be a good prospect that Mr. C. A. Luke will take a mill into Bradshaw district. The Crook mill has closed down for the present, on account of the snow in the mountains in that vicinity. At the Salvador mine, on Lynx creek, which is a gold-bearing ledge, there are 175 tons of first-class ore on the dump. The last ore worked on this mine yielded an average of \$60 per ton. In the Peck district, Joseph Minges has located a silver ledge called the Monitor, and Angus McKinnon and three others have located the Little May ledge. Fred Williams has located a good ledge in the Exchequer lode, in Peck district. Fred McIntire who is in from the Santa Maria placers, where he has been dry washing on a claim abandoned by some Mexicans, brought in some very fine coarse gold. Some of the pieces were worth as much as \$20, and he had some smaller pieces ranging from \$2 to \$10, amounting to \$120 in value. Harry Ashton and John H. Berry have bought places at the mouth of the Crook mine, upon which they intend to go to work immediately. A rich strike has been made in the Silver Flake, in Agua Fria district. The shaft is now down some \$3 feet and the ore at the bottom of the shaft and in the drift is richer than any before found in this rich mine.

Colorado.

THE RISE.—*Colorado Miner*, Jan. 27: The rise in the price of ore and silver has caused all sorts of speculation, and has been the cause of much excitement. It is gratifying to the deserving boys who handle pick and drill.

GREEN MOUNTAIN.—Work is actively progressing on this lode on Leavenworth mountain, and it is already turning out rich ore. The last run had by the lessees, Messrs. Smith and Scott, gave a return of 1,168 ounces silver per ton for first-class, and 537 ounces for second-class. The last report Messrs. Green & Tarbell have been timbering shaft and doing other development work. The drift has been run and shaft sunk a short distance, the latest working revealing the best mineral yet struck in the mine, ore carrying 15,000 ounces silver, and some showing masses and wires of native silver.

The total number of mining claims recorded in Hinsdale county up to the first of the new year was 1,550, of which number 900 was recorded during the year 1876.

Idaho.

MINER OF OWTZIE.—*Idaho Avalanche*, Feb. 3: At the Golden Chariot work is progressing under the most promising auspices. Large quantities of high grade ore have recently been taken out and there are several hundred tons ready for crushing. The existence of a very rich ledge is now placed beyond the shadow of a doubt, and an unbroken continuity of the same to the surface is vouched for by practical men, though it is not accompanied with the mine. That there is a combination of the most valuable mining property in the country embodied in the several claims of the Golden Chariot company, we have now the best evidence. Since the present Superintendent assumed the management he has, at a small outlay, placed the company in possession of the Crane & Driggs and Ewsdale ledge, the first of which was at one time the richest mine in the camp. This fine property turns out to be a most opportune purchase for the Golden Chariot, as the ledge unites with one of the principal veins going east from the Chariot and both are known to be very rich as far as developed. Work has been progressing on a small scale at the Illinois Central for the past few weeks. Mr. Thomas Kilde has had a limited number of workmen employed there and several tons of rich rock have been taken out. A few days ago Mr. K. exhibited to us a quantity of the ore taken out which, he believes, will yield over \$275 to the ton. From the Wagontown mines favorable reports continue to be received. Some of the ore sent here from this camp during the past

Continued on page 92.

Continued from page 82.

are now but just beginning to see the realization of their hopes.

The Territory seems to be traversed from north to south by a continuation of great mineral belts, connected with the mineral deposits of Nevada and Mexico. The most western of these runs through Mohave and Yuma counties, parallel with the Colorado river, and varies from 30 to 50 miles in width; on it are found several notable mines, as the McCrackin, Keystone, Cupel, Fairfield, Hackberry and Planet, in Mohave county, and the Peacock, Isabella, Constantia and Castle Dome, in Yuma county. Eastward from the Peacock range of mountains, in which the Hackberry mine is situated, is a strip of country 75 miles wide, in which there is no mining carried on, nor have any mines of value been discovered, and much of the surface is covered with volcanic rock, which gives out in the neighborhood of Prescott, where the Sierra Prieta range looms up, formed of granite, porphyry and slate, and the mines of Yavapai county are found in a mineral belt, 50 miles wide, extending eastward to the Verde river, one of the main branches of Salt river, and southward into Sonora. On this belt are the settlements of Prescott, Lynx Creek, Walnut Grove, Weaver, Antelope, Aqua Fria, Black Canyon, Wickenburg, Alexandra and Bradshaw, near many productive mines, from several of which ore has been shipped to San Francisco, yielding good returns, and which are supplying the various reduction works of the county at the present time. The best known are named the Peck, Prince, Senator, Union Pacific, Kit Carson, Silver Belt, Silver Flake, Accidental, Davis, Crook, War Eagle, Grey Eagle, Tiger, Cougar, Vulture and Montezuma.

In a succeeding paper I will continue the subject, and so far as possible, give items concerning the production of bullion from the principal mines in the Territory, with the inducements Arizona offers to the mining public and for the investment of capital. H. A. B.

Prescott, Arizona, Jan. 15th, 1877.

The United States Arsenal at Frankford.

The following description of the United States arsenal at Frankford was written by R. L. M. Camden, Jr., in a private letter to his father, R. L. M. Camden, of this city. The writer is a California boy of the best type, and his course in life thus far has been a credit to his native State. For the four years he has been in college his record in behavior, scholarship and high averages has never been excelled. With hardly a single exception he has always stood at the head of his class and he now has his hard earned degree of A. M.:

MY DEAR FATHER:—At the kind invitation of one of the officers of the United States arsenal at Frankford, I recently visited that institution, and thinking a brief description of it (as you had never been there) would interest you, I will endeavor to give it to you—preliminary, of course, that this description must, from necessity, be in that peculiar style known as the "pedantic school boy style." But so far as I can, I will try and avoid this troublesome Charybdis, and possibly, aye, probably, my efforts to do so will wreck me on the Scylla of no style at all. "There, there," methinks I hear you say, "that will do—another word and you will be wrecked before you fairly set sail."

You are aware that Frankford is not esteemed an aristocratic portion of Philadelphia, and yet there is much in its shaded streets and pleasant homes to make it attractive, and I am sure one ought not to complain, even though his lines are cast in such a suburb.

On entering the large and well kept grounds of the arsenal, I found myself in the presence of what I will call the negative form of "grim-visaged war." At all points the nature of the place is voiced in shot and shell and cannon. And though no ponderous columbiad frowns upon you from his well poised and imperial throne, yet enough of his children are scattered about the place to assure you that, if necessary, the air could be made to quiver with "explosions dire," and be filled with an iron storm that would make Destruction happy and cause Death to sing paeons of joy and triumph! In general terms I would say that the arrangement of the buildings is such as is dictated by convenience, prudence and safety. Nor has architectural effect been wholly neglected. For example, the officers' quarters are handsome buildings, with enough ornamentation to place them, if not in the category of the grand, yet in that above the common. They are nicely fitted up in the interior, and, though having a somewhat belligerent aspect, are nevertheless pleasant and agreeable. There are two houses on the grounds for the men (who at present number 30), one of which is occupied by the married, and the other by the single men. I am not advised why these laborers and artisans, married and single, cannot, or do not, live together, unless it be from the nature of their occupations and surroundings; these, being ever suggestive of disputes, wrangles and war, may impart such a contentious spirit to the men as to render the single and plural impossible to agree. Among other buildings there is quite a large one which was erected for a rolling mill (for copper), but there being at present not a sufficient demand for cartridges—for which the copper is used—no machinery has been put in the building. And I cannot help the prayer,

"May Heaven so order events that the machinery will never be wanted."

The first building I went into was what might be called the business building, that is, the bookkeepers, inspectors, secretary and others have their offices in it. In one office I was shown many specimens of

Experimental and Service Cartridges.

The United States service cartridge is what is known as the Springfield. There is shown a wrapped cartridge, that is, one formed of exceedingly thin brass wrapped by hand around the "former," and having a solid head soldered in. The objections to this are want of accuracy and the expense of manufacture. I say want of accuracy, although I do not doubt that a possible variation of 2-1000ths of an inch, above or below a standard, seems very little to most persons, and not worth making a fuss about, yet these critical and exact arsenal officers will not tolerate a variation of 5-10,000ths of an inch, above or below the standard! This looks like splitting hairs with a vengeance—but it marks the great superiority of stamped-up copper cases. A Gatling gun cartridge, made at the arsenal, is of the same general form as the Springfield rifle cartridge, but the ball is sometimes replaced by a sort of grape shot arrangement which makes it fearfully destructive. In fact, it can be made to rain shot thick as hail from a thunder cloud, and hurl death in horrid forms through ranks of men. Cartridges were shown me which were so arranged as to fire the powder near the ball first, and many kinds of fuses are made to be used by friction, percussion and electricity.

The Process of Making

The service cartridge is as follows: The copper is brought in sheets of the required gauge and subjected to the action of several stamping presses in succession. The first of these cuts out a circle of the required diameter and forms it into a shallow cup. The second, third and fourth presses gradually change this cup to a long cylinder, closed at one end. These are called cases, and are now fed to a machine which cuts them to the exact length desired; and lastly, the shell, or case, is slightly tapered towards the open end. There is now placed in the closed end of the cartridge case a "cup anvil." And this is a little shallow cup of copper having a depression in the center of the outside, with two small vent holes at the extremities of the diameter of the depression. Thus far the cup anvil has gone through four processes.

The depression is now filled with fulminate of mercury by a very ingenious machine, and is then ready to be placed in the shell. And this is accomplished by another machine, which at the same time crimps the copper around the edge of the anvil, thus holding it firmly in its place. The cases thus far finished, are now taken to another building, where they each receive a charge of powder and ball. The machine which charges the shells is very complicated, and seems almost endowed with human intelligence. Watching its motions, one will notice, among other things, that if a shell passes the feeder uncharged, it starts up and rings a bell, thus notifying an error in the work. The finished cartridges are packed in pasteboard boxes, 20 in each, which boxes are made by machinery at the arsenal, and are so shaped as to allow the cartridges to be taken out of any part of the box with perfect ease. These boxes are also furnished with a string by which they may be ripped open in an instant. They are finally packed in wooden cases, each case containing 50 boxes, or 1,000 charges, and are then stamped with the date of manufacture and packed away ready for use. The bullets used in charging the cartridges are of the Minie pattern, and the grooves in them are filled with a kind of lubricant. The lead for the balls is bought in the rough, and is rolled down to the proper diameter, and then pressed into shape. Cast bullets are not used because of their want of homogeneity. Attached to the arsenal is a carpenter's shop, where all the wood-work required is done. The powder magazine at present contains only 1,500 barrels, which, though comparatively a small quantity, is nevertheless enough, if fired, to produce a good edition of a California earthquake in and near Frankford.

In the Arsenal Ground,

Near the river, are placed two targets, one of which is 300 and the other 500 yards distant from a firing house. Near each target is a house protected by banks of earth, and supplied with a camera obscura, which throws an image of the target, reduced to one-twelfth of its real size, on a table at which an observer sits and notes the shots made. The observation and firing houses are connected by telegraph, and there are several instruments for finding the velocity of the bullets. One of the instruments measures the velocity by the vibration of a pendulum of a given length, and another by the vibrations of a tuning fork. A switch board enables the observer to register the velocity by all or any one of the apparatus in use.

I was shown specimens of all the finest breech-loaders in use, and also specimens of the Springfield rifle, both muzzle and breech-loaders. The change from the former to the latter was made in 1866. Mr. O'Reilly has invented a shell fuse which is so constructed that it will cause the shell to explode in a certain time, unless it strikes some object, in which case it instantly explodes. This fuse is very ingenious, and no doubt will accomplish the results claimed for it.

But I will not weary you with any further

description of this piece of property belonging to our venerable Uncle Samuel. Still, in bidding it adieu, I cannot help wishing that human nature may, sometime, be so inwoven with the bright elements of self-abnegation, love and peace, as to render arsenals useless, and shot and shell and cannon but so many mementoes of a past "dark age."

R. L. M. CAMDEN, JR.

Philadelphia, Jan. 15th, 1877.

Agriculture and Mining.

We take the following communication on the above subject from the columns of the *Pacific Rural Press*. It will be seen by the first paragraph that that journal reproduced from this an extended article on the subject, which has attracted considerable attention among the farmers. In order to show our mining friends the feelings of the farmers on the question, we give the annexed letter:

EDITOR PRESS:—In your issue of January 13th, 1877, is copied an article from the *MINING AND SCIENTIFIC PRESS* on the above question, and which has been extensively read and discussed in this vicinity. It is generally conceded that while it gives the views and position of the hydraulic miners with fidelity to their interests; it passes over lightly or ignores entirely the agricultural interests of our State while purporting to be a discussion of both interests. By your permission I would offer a few remarks on this (to us all) important subject, and would ask, if found worthy, for a space in your valuable publication.

There is a principle involved in this question that is as old as law itself. It is not a question of local importance or application. If this well established law and precedent can be ruthlessly violated in two or three counties in the State, it carries with it the right for any enterprise to crush out all antagonistic interests if necessary for its own successful prosecution. If we concede the necessity of sacrificing the agricultural portions of Butte, Yuba, Sutter and Sacramento counties to the claims of hydraulic miners, we virtually give up agriculture in California, and every interest connected therewith, at the call of this one interest, however remote it may be. In the name of our beloved State and her past, present and future history, her renowned accomplishments in agriculture and commerce, I protest against such a surrender as against all law and precedent; against our true State policy; as against robbing our children of their inheritance, finally, as against selling the glorious future of our State for present gold. Let us examine a few of the leading arguments of our mining friends and endeavor to see if they are treating us with deserved candor.

We are told we went upon these lands knowing the danger we subjected ourselves to. I deny this assertion. All our rich alluvial bottom lands were owned long before the discovery of gold. The land upon which the city of Marysville now stands was so owned and occupied, and the city itself named after the wife of one of our earliest pioneers, Mr. Coriand, whose splendidly improved farm in the suburbs of the city, consisting of orchards and vineyards, houses, barns, etc., have all been covered up and destroyed by this "lava" of sand and mud, and the proprietor and his wife, "Mary," are inhabitants of the city of the dead and their children bereft of their true inheritance.

The whole Yuba river valley was occupied before there was a hydraulic mine in existence; the same is true of the American, Bear and Feather rivers. Mining as prosecuted in this State the first ten years did not materially injure these lands. It is not denied that these lands were periodically overflowed, but these deposits rather enriched them otherwise, and no injury resulted until the year 1862. To guard against this debris at the time of settlement would have been to waste means on an imaginable evil that might never have come.

We are also told that because the mines furnished us a market for our products we have no right to complain; that our profits were equal to theirs and dependent on them. I concede the truth of this only for the first few years of agricultural experience, after which our market over-leaped the bounds of California and the United States, and our products were sought by the people of Europe, Asia and Australia. To this epoch dates our great prosperity as a State, and our commercial importance. Our mines furnish the agriculturists not a tithe of a market for this surplus.

But we are told that it would not do to interfere with hydraulic mining, as the precious metals are required by our government to enable it to preserve its credit and to assist it to resume specie payment. I would ask in all candor—Shall we be sacrificed that the government may flourish? The position is utterly untenable. I will not occupy space to refute such a monstrous proposition. Our friends in their distress are seeking to unite the entire mining interest on the Pacific coast in an offensive and defensive alliance against the farmers. Now, it is well known that we have no complaint to en-

ter against any but the hydraulic process; all others as yet are not encroaching upon our rights or interests. We are only asking for that consideration and protection that is vouchsafed to the humblest miner as against his neighbor. There is an old and trite saying, "whom the gods would destroy they first make mad." The alliance spoken of will necessitate a counter alliance by the farmer and his sympathizer, and then it will go into politics. In my opinion it will not require a very far reach of imagination to foretell the end.

We are told that some of the leading mine owners attempted to procure seasonable legislation on the subject at the last session of our legislature. Now, we happen to know that the very reverse is true. The agriculturists made such an attempt to have the subject examined in all its bearings by a committee, together with competent engineers and report their observations to the next legislature. But this reasonable request was denied us by the miner, and the best we could get was a resolution calling the attention of congress to the subject. When they get through making presidents we may hear of the resolution and we may not. If the object was to gain time, the miner could not have chosen a better course. However, the miners did offer a resolution looking to State investigation; but the Commission was instructed to report the great benefits to the farmers of this detritus to their lands, past, present and prospective. Now, if that was not jesting it was an insult, at least could not be accepted by the farmers.

Finally, it is suggested that miner and farmer unite and conduct this sediment to the great tule marshes, and thus reclaim them. At first thought it seems feasible if the means were provided. But on fuller investigation, I apprehend it will be found to have insurmountable objections. The greatest that presents itself to my mind is that these great tule lakes serve as a receptacle or reservoir for the great surplus waters that periodically precipitate themselves into the inland valleys in a few hours. The natural fall of these valleys and their rivers being insufficient to carry the waters to the bay as fast as received from the mountains, it would follow that the entire valley would be inundated if these tules were reclaimed as proposed. I am confident that a scientific examination would find this the greatest obstacle to be overcome.

I have made no allusion to the great destruction already accomplished, that was largely done a year ago; although made light of recently, it yet remains a stubborn fact. But I prefer to address myself at present to the saving of what yet remains to us. Much money has already been spent in constructing works to keep off this detritus, and much more will have to go the same way. But that we shall ultimately triumph, I have no doubt, for this valley is too valuable to be given up for a dump to the hydraulic miner.

Let me foreshadow the final decision of this question, for I have no hope that the miners will accept anything until driven to it.

"The waters of the State belong to the people of the State for purposes of navigation and the use of man and beast. No one will be permitted to use it to the injury of all others." Every industry must be so conducted as not to injure any other industry of equal paramount importance." When this is done the cloud that now overhangs us will clear away, and agriculture asks no more. GEORGE OHLEYER.

Yuba City, Jan. 29th, 1877.

Lincoln and Ione Coal.

The Ione coal, from which so much has been expected, has been tested and found wanting. It has been used at the water works and in various mills in Sacramento, and, compared with the coal at Lincoln in this county, is only worth about two-thirds as much. The Ione coal is delivered in Sacramento at \$4 per ton, while the Lincoln coal was sold at \$5, yet the former, compared with it for steam-making, is worth only \$3.43. The building of the branch road to Ione was undertaken mainly to secure a supply of this coal, and it may occur to our readers to ask why a road was built to a coal mine when one was already open on a line now in operation. The solution of this problem is easy. The railroad company wish to use large quantities themselves, and they also desire to monopolize the trade in this article along their lines. The mines at Lincoln are in the hands of private parties who ask a high price for them. Those at Ione are owned by the company, and they considered it cheaper to build a road to them than to buy the Lincoln mines. Partly in consequence of the high price at which their inferior coal has been held, the Lincoln mines have suspended, though capable of producing large quantities of cheap fuel with profit to their owners. We do not think the proprietors are acting wisely. We have been assured that their coal can be mined at a cost of 60 cents a ton. It surely can be delivered in Sacramento at a profit for less than \$5 a ton, and now that it has been shown by actual test that two tons of Lincoln coal are worth three tons of the Ione article, we think the proprietors ought to take steps to work their mines, the first and most important one being to place it on the market at a price that will make it a cheaper fuel than wood. This county is deeply interested in the development of all its resources, and the coal-beds at Lincoln have been regarded as one of its most considerable elements of wealth.—*Placer Herald*.

How Bullion is Produced.

We have mentioned our furnaces in a desultory way, but do not remember having seen any detailed description of their workings, although it is generally conceded that the furnaces in use here are as perfect in construction and capacity and do closer work on argentiferous ores than any in other localities. In fact, a smelter who has acquired his knowledge at the Eureka furnaces, has a reputation that no other place gives, sort of guarantee of competency. All the furnaces in Eureka, with the exception of two water-jackets at the Richmond, are modifications of the Raschette and Piltz furnaces, altered and improved to suit the combinations and qualities of the ore smelted. They are built of stone from the quarries in the vicinity, and lined with a porous fire-proof sandstone, of excellent quality, from Pancake mountain, about 20 miles distant. The inside diameter will average 4½ feet at the hearth, and the height to the charging windows is about 16 feet. The hearth rises about 2½ feet from the ground and projects 18 inches from the mouth in the front of the furnace. On three sides and one foot above the hearth, eight tuyeres pierce the shaft, three on each side and two at the back. The shaft is carried through the floor and the charging windows open on the second story, or ore floor of the works, but the masonry extends to and through the roof, connecting with the flue or fume arrester. The tuyeres are double wrought iron pipes, a space intervening between the outer and inner pipe, through which a constant current of air flows, preventing the melting of the tuyeres where they are exposed to the fierce heat. The blast is furnished by a Root blower, with a capacity of 600 revolutions per minute, and is conveyed to the tuyeres by a system of tin pipes and canvas hose. The front of the furnace is open to a height of 10 inches, the space between the melted slag and masonry being temporarily filled with a mixture of fire-proof clay, and removed at the pleasure of the smelter, when it becomes necessary to "bar out" or remove the slag. At the side is the lead well, connected by a pipe with the bottom of the furnace, the lead rising to the same height in the well that it attains in the furnaces. The projecting hearth is supplied with two spouts, through which the iron and slag are drawn off into the cast-iron slag-pots. In the working process the furnace is filled with the ore mixed with a certain proportion of charcoal. Fire is applied, the blast turned on, and the furnace is in operation. The ore smelted is argentiferous galena, and contains from 40 to 60 per cent. lead, some iron, sulphur and arsenic. The heat concentrated on the ore at the mouth of the tuyeres, will reach 2,000° Fahrenheit, and under its influence the metals contained in the ore and the silica or quartz melt and flow to the bottom of the furnace. The lead, from its greater gravity, goes to the bottom, carrying with it the precious gold and silver. On the top of the lead the melted iron floats, and on this again swim the lighter materials termed slag. As the lead accumulates it is ladled out from the well into molds, forming base bullion bars, averaging 120 pounds in weight. These bars will assay from \$200 to \$400 per ton, varying with the quality of the ore smelted. Each charge is composed of 46 shovelfuls of ore, intermixed with 12 bushels of charcoal. No flux is necessary, with the exception of a shovelful of silica or slag, as the ore smelt freely. One of the furnaces at the Eureka Consolidated, now running, was built for a reduction capacity of 50 tons per day, but it goes considerably above this, averaging 65 tons every 24 hours, and has reduced as high as 90 tons, producing 10 tons of bullion.

The working force consists of one smelter, two slag-wheelers, two feeders and three ore and charcoal tenders. The smelters receive \$5 per day of eight hours, and wheelers \$4. The work is rather unhealthy—those most exposed to the fumes being subject to lead paralysis; but of late the attention paid to ventilation has remedied this in a great degree.

As we stated in the commencement of this article, there is no place in the world where smelting has attained a higher degree of perfection, and we are constantly improving our methods and processes. —Eureka Sentinel.

Electric Signals for San Fernando Tunnel.

Mr. J. R. Scupham, engineer of the Southern Pacific Railroad Company, is at the San Fernando tunnel, for the purpose of superintending the work of placing electric railroad signals therein. The signals to be employed are known as Robinson's patent wireless electric railroad signals, and they are simple in construction and reliable in operation. They are to be placed, one at each entrance to the tunnel, the connection between the signals being made by means of the rails. A train entering the tunnel connects the two rails together by means of the axles of the engine and cars, cutting off the galvanic battery current, causing the signals to show a red flag at each end of the tunnel, thus warning other trains from entering while the track is occupied. When the train passes out of the tunnel, the electricity again passes along the rails, charging the signals and removing the red flags from view. A break of the rails or a failure of the battery or any derangement of the apparatus, causes red signals to be shown. These signals are being put in place by the Electrical Construction and Maintenance Company, of San Francisco. —Los Angeles Express.

USEFUL INFORMATION.

Instructions for Handling and Using Tri-Nitro-Glycerine.

The following rules are laid down by Mr. Mowbray, in his excellent treatise on "Tri-Nitro-Glycerine," viz.:

1. Handle carefully, avoiding a sudden jar or concussion, and be very careful, if any is spilled outside the can, to avoid striking it against any hard substance.
2. When solid, thaw out by placing the cans in a tub of warm water, not hotter than the wrist can bear, first pouring warm water into the can, and always remove the can before adding more hot water to the tub.
3. To fill cartridges, etc.: Hold the cartridges to be filled over a tray, say two feet by three feet, the bottom of which should be covered with plaster of paris (which will not readily explode when saturated with nitro-glycerine.) The soiled plaster of paris should be frequently renewed.
4. If nitro-glycerine in a liquid state is kept in a store or magazine for some time, the cork should be loosely inserted, and a pint of cold water poured into each can, to be frequently poured off and replaced with fresh cold water in warm weather, taking care to retain the bladder under the cork. It is preferable, when ice can be procured, to congeal the nitro-glycerine.
5. Use funnels (gutta-percha, if they can be had) for filling water holes. Under no circumstances whatever attempt to tamp the drill holes; it is unnecessary, and may kill the man who attempts it.
6. Hot irons to warm the water, or for soldering the cans, will be sure to cause explosions.
7. Never sledge or attempt drilling in a hole or seam where nitro-glycerine has been spilled; fire an exploder, which will effectually clear it up.
8. Never pour nitro-glycerine into a hole unless perfectly sure that it is a sound hole, or will hold water; if seamy always use cartridges.
9. To obtain the best results with nitro-glycerine, drill deep holes, six feet or more. Use powerful exploders and well insulated wires. It is cheaper to fire by electric battery with simultaneous explosion, than to fire several holes with tape fuse.
10. Look out after a blast for any unexploded cartridges lying around.
11. Never allow any but the most careful persons to handle or have charge of the nitro-glycerine, and insist upon the use of every precaution to prevent an accident or explosion.
12. Never allow empty glycerine cans to be used for any other purpose, but destroy them by a fuse and exploder, or by building a fire under them; first, however, removing them to a safe distance.
13. Examine your cans from time to time and notice if, at the level of the nitro-glycerine, any pin holes have eaten through; in such case procure a new can, or stone jar, and empty the contents out, not trusting your hold to the upper part of the can, lest it may give away.
14. When solid or congealed it is absolutely safe; if possible, therefore, any surplus should be stored surrounded with ice, since no explosion can take place when it is solid.

AN INVENTOR WANTED.—The *American Manufacturer* says: It isn't a new notion, but a leading Georgia cotton planter is renewing and emphasizing the demand for a cotton-picker that shall do for cotton what the reaping machines do for the grain crop of the world. Since the invention of the cotton-gin nothing is so much needed in the South, and there can be but little doubt that the man who solves this mechanical problem will win not only fame but fortune. It is not necessary, says the planter, that the cotton-picker should do its work cleanly; if it can but garner two-thirds or three-fourths of the crop, manual labor will take care of the remainder. The customary price of picking cotton by hand is 75 cents per 100 pounds of seed cotton, the average yield of which, in marketable lint, is 33 pounds. The cost of hand-picking, therefore, is 2½ cents per pound, a very large item, which ought to be reduced, by appropriate machinery, by more than one-half. A successful inventor, who should exact as his royalty only one-eighth of one per cent. per pound upon the cotton crop of the United States, might fairly figure his annual income at more than \$3,000,000, a sum worth striving for by any mechanic who has the gift of invention.

LEECHES AS WEATHER PROPHETS.—The *Journal de Medecine de Bruxelles* states that a leech will prove an accurate barometer: Into a flask of the capacity of 1½ liters (about 45½ fluid ounces) pour one liter (about 34 fluid ounces) of water, introduce a leech, cover the bottle with coarse linen and place it in the window. If the leech remains motionless and coiled up at the bottom, this indicates lasting fair and clear weather, in summer or winter. If the leech ascends into the neck, rain or snow will follow, during which time it remains above. If windy weather is approaching, it swims about restlessly, and ceases only to do so when the wind abates. A few days before a severe thunder-storm with rain, it remains entirely outside of the water, and throws itself about, apparently in convulsions, from one side to the other.

GLASS VENEERS.—A company was recently formed in New York for the purpose of manufacturing, as they term it, "glass veneers and decorations on glass." Specimens of their work are said to be excellent imitations of the various woods represented—such as birch, ash, French walnut, grey maple, rosewood, mahogany, bird's-eye maple, satin wood, etc. For panelings, wall and ceiling decorations, marquetry, imitations of the different marbles, tiles, etc., we know of nothing to equal this new manufacture, and predict for it a great success, combining, as it does, cheapness and beauty. Mr. Budd, the inventor, has had a single pianoforte in use for the past two years, covered with glass veneer, during which period it has been removed three times without breakage, or even a scratch.

SKIN CURING.—An Australian correspondent recommends the following method of preserving opossum, otter, and other small skins, as the result of 15 years' experience. A very strong decoction of fresh bark of wattle saplings should be prepared beforehand. Into this the skin is thrown as soon as it is stripped from the animal, and left for eight days; it is then taken out, fleshed, and returned to the liquor for a couple of days more; lastly, it is pegged out to dry. The skin will then be perfectly cured, impervious to rain; the fur well set, and with a nice lustrous appearance.

COFFEE LEAF TEA.—A correspondent, in a measure apparently prompted by the gradual deterioration in quality of Chinese tea, advocates the use of a decoction of coffee leaves, and the introduction of Mate or Paraguay tea. Mr. Alexander, of Redbank, as stated in the *Queenlander*, it appears, showed at the exhibition then recently opened at Brisbane some coffee tea, prepared from the leaves of trees growing on his estate, stating that the beverage prepared from these leaves was delicious, and far preferable to that obtained from the berry.

WEIGHT OF BELTS.—Rankine says: Leather belts, when new, are not quite of the heaviness of water—say about 60 pounds per cubic foot; but, after having been for some time in use, they become thinner and denser by compression, and are then about as heavy as water. The weight of a single belting may be approximately estimated at 0.068 pounds per foot, length and inch breadth.

GOOD HEALTH.

Sunlight Necessary to Health.

In his last quarterly report, Dr. John Liddle, the medical officer of health for the White-chapel district, says: I firmly believe that many persons who are compelled to occupy rooms in which the rays of the sun never enter, soon lose their health, and find it necessary to change their residence; and this remark applies, although perhaps with less force, to those who are confined to counting-houses during the day in which no sunlight is admitted. Sunlight is especially necessary for the healthy existence of children; and this is strongly pointed out in the evidence of the late Mr. N. B. Ward (the inventor of the "Wardian cases," for rearing plants in towns, and conveying them to and from distant places, a gentleman of great eminence in the medical profession, and who has given much attention to the influence of the temperature, of air and light upon the health and growth of animals and plants) who says, in his evidence before the commissioners appointed for inquiry into the state of large towns and populous districts, that, as the result of his experience, the influence of light is a matter of the highest importance to the proper physical development of the human species; and whatever stunts the growth of a child certainly operates upon his physical capacity for labor; that the amount of disease among persons occupying light rooms is infinitely less as compared with that in dark ones; and that the influence of light, especially solar light, in preventing the fatal termination of disease, is a fact well known to him. In further illustration of this subject, Mr. Ward quotes a fact stated on the authority of Sir James Wyllie, "that the cases of diseases on the dark side of an extensive barrack at St. Petersburg have been uniformly, for many years, in the proportion of three to one to those on the side exposed to strong light." —Public Health.

HIGH HEELS.—Prof. Sayre speaks of a form of what we may call fashionable disease: Accident may occur in descending stairs or steep declivities while wearing high-heeled shoes, which throw the weight of the body upon the front part of the foot, and the extra effort made for the purpose of retaining the body within the center of gravity produces a direct strain upon these tendons, causing rupture or stretching of the annular ligament sufficient to allow them to be displaced. It is no wonder then that fashionable women waddle in a most ungraceful manner when they attempt to walk. They destroy their comfort to follow a ridiculous fashion, and acquire an ambling and undignified movement. People do things to follow fashion that their good sense would cause them to be ashamed of under any other circumstances. Ladies wearing such shoes are often obliged, for safety, to go down stairs backwards; and our author says that they can be seen "every day descending the stoops of our fashionable residences in this manner, making pretense of talking to some imaginary person in the front door as an excuse to hide their awkward movements."

Lead Poison in Sewing Silk.

The *Moniteur d'Hygiene* startles its readers with the revelation of an ingenious fraud, not generally known, but likely to be in the long run very dangerous to the health of tailors, seamstresses and others who use silk thread in sewing. Nothing is more pernicious to the system than lead, and yet it may be constantly introduced into the stomach by those who use sewing silk. The fact is important if lead be the metal used for giving weight to silk. Lead acts very surreptitiously on the system; it is essentially "a slow poison," and it is very difficult to combat its effects. It acts on the teeth and on the intestines, in which it produces paralysis, frequently followed by death. "We have seen," says the writer in the *Moniteur d'Hygiene*, "among other cases, that of a lady who keeps a large sewing establishment, who, by the use of such silk thread, was, together with her workwomen, attacked by lead colic, some of them losing their teeth—the result of the habit of putting the ends of the silk into the mouth before passing it through the eye of the needle. Such is the way in which the lead poison is directly absorbed, whilst, by continually handling the silk, the fingers may retain a portion of the lead, to be indirectly introduced into the system with the food that may be touched by the hand. The poison may be avoided by refraining from putting the silk into the mouth—dipping it in gummed water instead—but perhaps the best remedy will be found by the large dealers refusing to buy silk thread by weight unless it is proved to be free from metallic adulteration.

FOOD FOR IMPERTEMPERANCE.—A writer in the *Herald of Health* on the "relations of intemperance to food" makes this point: What is the remedy for intemperance? I answer, nerve food—building material to supply the waste of the nervous tissue in the masses. I answer, further, a reform in the present popular system of dietetics, by reducing the proportion of fat and muscle forming elements, and increasing the nerve and brain building material in a proper ratio. Let the supply in each case meet the demand and no more. A study of this subject, and a practical application of the theory that I am advocating for the past 15 years, gives me a solid basis of fact on which to rest its advocacy. Food beverage—a liquid food composed largely of brain and nerve building elements, a combination, concrete, soluble, and one that is so rapidly taken into the circulation that the patient feels immediately its invigorating, energizing power, has proved in my hands an almost certain remedy. It at once, and at the same time, allays thirst and invigorates without stimulating, imparting to the system a permanent basis of nervous vigor and energy.

PHYSICAL TRAINING.—Mr. MacLaren, on physical education, says: "However weak the boy, gymnastic exercises under proper training must be beneficial; use gives facility of execution, and facility of execution causes frequency of practice, because we all like to do that which we can do well; and thus eventually, being based on the organic law of development, the weaker parts may, by proper cultivation, be strengthened. Systematized exercises can modify the growth and distribute the resources of the body, so that each particular part shall have its legitimate share, and so increase the resources that each part of the growing frame shall have its wants supplied. During growth it is possible to add to proportion, consolidate and sustain every cell of every fiber or tissue as it is added to the frame; after growth this is not probable, but it is still possible; aye, still a certainty, to recover a valuable portion of the material well-being of every man, and add to that strength and vital stamina which will help him at all times, at all seasons and under all trials."

APPETITE AND WORK.—Pavo says that a falling off of the appetite indicates a diminished capacity to labor. A farmer was once asked why he paid his hands so much, replied, it was economy to pay them well, so they could buy sufficient food. One might as reasonably expect much labor from a meager diet as much fire from a little wood. A good appetite is generally synonymous with health and ability to do much labor. Great workers, whether by body or brain, or both, are usually liberal eaters. Lawyers and ministers are apt to be good eaters. They should eat wisely as well as liberally, otherwise, dyspepsia will be the result. The old notion that great thinkers are small eaters is incorrect, except in the case of those who live very quiet and inactive lives. —Dr. Holbrook.

DANGEROUS IVORY.—For some time past the market is supplied with a substitute for ivory, which, owing to its cheapness, bids fair to curtail the use and sale of genuine ivory goods in many respects. But this peculiar compound has two great disadvantages. One is, that, by handling it with warm, moist hands, or attempting to clean it with water, it becomes soft, swells up, and gets sticky. But the other drawback is more serious. Its composition being water, 80.80; lead peroxide, 16.04; barium sulphate, 26.05; glutine, 34.21; and various other less important substances, the employment of this compound in the manufacture of toys for children, mouth-pieces, eating utensils, etc., is highly dangerous. —New Remedies.

MINING SCIENTIFIC PRESS

Four weeks are rated as one month.
Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing in extraordinary type or in particular parts of the paper inserted at special rates.

SUBSCRIPTION IN ADVANCE.—Postage paid—one year, \$4; six months, \$2.25; three months, \$1.25. Remittances by registered letters or P. O. orders at our risk.

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription.

THE ORIGINAL ARTICLES in this paper are mostly set in solid type, giving in our columns one-third more reading than is contained in ordinary leaded matter.

Address all letters to the firm, and not to individual members, or others, who may at any time be absent.

Our latest forms go to press on Thursday evening.

SAN FRANCISCO:

Saturday Morning, Feb. 10, 1877.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Comstock Papers.—No. 10; Flexible Power Transmitter; Whip-Making and the Effects of Steady Employment; Useful Device, 81. Mining Share Market, 84. Miners' Wages; Locating Claims for Friends; Twelfth Industrial Exhibition of the Mechanics' Institute, 88. The "Packsaddle," Academy of Sciences; Mechanical Ore Concentration.—No. 21, 89. Notes on a Bruckner Roasting Cylinder, 92. Notices of Recent Patents, 93.

ILLUSTRATIONS.—The Stow Flexible Power Transmitter, 81. The "Packsaddle," Conemaugh River, Pennsylvania, 89.

CORRESPONDENCE.—Mines of Beaverhead Co., Montana; Arizona as a Mining Country; The United States Arsenal at Frankford; Agriculture and Mining, 82-86.

MECHANICAL PROGRESS.—A Crack in the Great Gun; Design in Steam Boilers; Machines in New South Wales; Starting the Drill, 83.

SCIENTIFIC PROGRESS.—The Laws of Taste and Smell; The Wheeler Survey; The English Believe in the Sea Serpent; The Distance of the Sun, 83.

USEFUL INFORMATION.—Instructions for Handling and Using Tri-Nitro-Glycerine; An Inventor Wanted; Leeches as War Prophets; Glass Veneers; Skin Curing; Coffee Leaf Tea; Weight of Belts, 87.

THE ENGINEER.—Chemistry Applied to Engineering; Changing the Course of the Danube; Engineering Items; The East River Bridge Cables; A Dam, 90.

MINING SUMMARY from the counties in California, Nevada, Arizona, Colorado, Idaho and Utah, 85-92.

MISCELLANEOUS.—Lincoln and Ione Coal, 86. How Bullion is Produced; Electric Signals for San Fernando Tunnel, 87. The Battle Creek Mines in the Black Hills; The Nevada Bullion Tax; Home Encouragement for Mining; Shipping Ores from Idaho; Manhattan Mine, 90. The Eureka Lake Water and Mining Company; Fish Spawn from the East; Condon Mill Leased; Alps Mine; Richmond Assay Office; Second Bridge between New York and Brooklyn, 91. Items of Interest from the Mines; Manhattan Mining Company, 92. The Bressa Prize for Scientific Work, 93.

NEW ADVERTISEMENTS.

Hotel of the Netherlands, F. Meyer, Manager, Port Said, Egypt; Webster's Dictionary, G. & C. Merriam, Publishers.

METEOROLOGICAL.—The movement for the application of the Signal Service to the practical observation of the Pacific coast weather, and the foretelling of storms, etc., is advancing. At the last meeting of the Academy of Sciences Dr. Gibbons proposed the formation of a section in meteorology, as the Signal Service at Washington desired to open communications with a scientific source on this coast, and steps were taken to carry out the idea. Professor Davidson stated that the Central Pacific railroad had 50 signal stations from the Rocky mountains to the Gulf of California, and that the observations had been full, reliable and of considerable use, and regularly reported to the Smithsonian Institute at Washington. It was now proposed, by a number of private gentlemen in this city, to establish nine meteorological stations on the North Pacific, from Alaska, where the United States Government is about to establish a tidal station, through the Aleutian islands to Kamchatka. Dr. Gibbons said that this subject was of great importance to the agricultural and mining interests of this coast.

By the suspension of Congressional work at the public printing office in Washington about 600 persons were thrown out of employment. The Public Printer has no money, except the unexpended balance of appropriations to departments and the congressional library, and for printing the proceedings and debates of Congress.

The testimony in the case of Henry D. Bacon, and other stockholders in the Morgan mine, against William Irvine and the management, brought before the Nineteenth District Court on motion of defendants to remove the temporary injunction, was concluded Tuesday. The motion will come up for argument on Monday next.

Miners' Wages.

The agitation of the question of reducing miners' wages has commenced, and a few companies have already inaugurated the movement. At Smartsville, Yuba county, a notice was posted, on the 23d ult., stating that after February 1st, all wages heretofore paid mine laborers would be reduced fifty cents, signed by all the companies except the Blue Point and Nevada Reservoir ditch companies. The reduction of wages extends to all the gravel mines in the northwestern portion of Nevada county. On the date mentioned the reduction of wages of fifty cents per day was put in force by all the companies except the Union, which continued to pay \$3 per day. The miners formed a procession, with a brass band, flags, etc., and marched around in an orderly manner to all the claims, requesting the men at work to join the procession.

The North Bloomfield gravel mining company gave notice, through its superintendent, that from the 1st inst., all men in the steady employment of the company should receive daily pay of \$2.75 from the 1st of December to the last of May, and from the 1st of June to 1st of December, \$2.50 per day. The San Juan Times says some of the miners say that they will not stand the reduction; others think it useless to try to resist the mandate of so strong a corporation, therefore they bow to the inevitable; still others argue that the reduction is made use of as a feasible and sure method of eliminating the white laborer, thus affording a plausible excuse for filling the vacancies by the cheaper Mongolian.

In connection with the labor matter, an organization called the "Caucasians" has been formed, and the Caucasian camp at San Juan now numbers 150 members. It numbers among its members people residing at Columbia Hill, Badger Hill, Cherokee, San Juan, Sweetland, Birchville and French Corral. The object of the Order is to get rid of Chinese labor, and to induce capitalists to employ white labor instead. Our Nevada county contemporary, the *Foot Hill Tidings*, says that V. G. Bell, of French Corral, Superintendent of extensive mining operations there, and who now employs about 170 Chinamen, as we are told, offered to discharge them provided the camp will supply their places with white labor at \$2.50 per day. Commenting on this fact, the *Grass Valley Union*, another journal in the same county, says: "We do not agree that the proposition is so very reasonable, and we do not see that the Order of Caucasians will do much for the cause of the white labor if it enters the market and goes to bidding down the price of labor as against the Chinamen. We fully understand that no camp of the Order has yet proposed to do that thing, but we are not as yet informed as to what action the San Juan camp has taken on Col. Bell's proposition. It is probable that the company represented by Col. Bell has already determined to reduce the wages of white miners to \$2.50 a day—indeed we are quite certain of that fact—and it may be good policy to have the Chinamen ousted from the gravel mines and white men put in, under the inevitable reduction that is coming. In other words, it does not look like sound policy in having the wages of such white miners as may be employed reduced to the figures named, and then have Chinamen still retained in such great numbers, to do most of the work."

The discussion on this subject promises to be a hot one, as the miners are naturally unwilling to accede to the reduction, as, once reduced, the wages are not likely to be raised again. The reduction of even half a dollar a day among these men will be severe to them, as few of the working miners have any store laid by. The cost of living in the mining localities allows no very large margin, and those miners with families are compelled to economize as it is. It must be confessed that the large companies have the best of the matter, as they hold the purse-strings, and men will work for little rather than not at all. The matter, however, lies between the miners and mine owners, and the miners understand the situation well enough to take care of their own interests. A miner's life is hard and dangerous enough under any circumstances, and he ought, at least, to make a comfortable living. We are not fully informed of the cause of the action of these companies, but the reduction is the beginning of an agitation of the wages question, which it will probably take some time to settle.

BULLION SHIPMENTS.—Since our last issue shipments from the prominent mines have been as follows: Tybo Con., January 27th, \$4,287.79—total to date, \$44,249.06; Manhattan, 31st, \$11,500—total to date, \$100,310.45; Chollar, 31st, \$4,217.89; Northern Belle, 30th, \$10,186.74, Feb. 1st, \$10,079.64; California, Feb. 3d, \$167,939.19—total to date, \$1,161,023.12; Con. Virginia, Feb. 3d, \$63,866.97—total for January account, \$519,346.85; Empire, Feb. 2d, \$17,782; Leopard, Feb. 1st, \$5,054.20; Gila, Jan. 30th, \$2,460; Modoc, Feb. 3d, \$5,610—total for February, \$11,290; Tybo Con., Jan. 31st, \$4,477.44—total to date for January, \$48,726.50; Manhattan, Feb. 6th, \$12,900.

The steamer *Ethel* has been wrecked on the English coast, and nineteen persons drowned.

Locating Claims for Friends.

One of our mining friends writes us and says: "Can a resident miner of any of the mining districts on this coast locate and hold a mining claim for any relation or friend, if such individual is a resident of any of the Eastern States?"

There is nothing in the law preventing such action, and it used to be common enough throughout the coast. Since the passage of the law of 1872, however, this is not done so much as formerly, as now one man can take up the whole 1,500 feet for himself. Under the old law, when the discoverer could only hold 400 feet but could locate as many other people in with 200 feet apiece as he chose, they used to resort to this, get deeds back from the others and hold the ground alone. This is not necessary now.

The law simply states that locators must be citizens of the United States. There is no more reason why, when the mine is in Nevada or Utah for instance, a person living in New York or Florida could not be located, than one living in California. Lots of people living in this city have claims located for them in other States and Territories. We have carefully examined the law and decisions under it and can find no reference which would prevent any one in the East being located in a mining claim here.

Of course the law is binding on all, whether residents of the mining district or not, and the annual expenditure must be made, in failure of which the mine is subject to a relocation. In case of any legal proceedings as, for instance, in the case of a contest of patent, it would, perhaps, be necessary for the owner to be in the district. Some time in 1873, the Commissioner of the Land Office rejected an adverse claim to a patent because it was not sworn to, as required by law, in the district where the land was situated. If we remember aright, it was in the case of the Dardanelles company, in Gold Hill district, Nevada, when they applied for a patent for the Bosphorus. The California company filed a protest through its President. The protest was sworn to before a Commissioner of Deeds for Nevada, but was sworn to in this city. The Commissioner ruled that the law required an adverse claim to be sworn to before some officer authorized to administer oath within the land district where the claims were located, and the adverse claim was accordingly rejected.

Although, as far as we know, there is nothing to prevent the practice of which our correspondent, and many others, complains, it is none the less an objectionable custom. No individual should be allowed to come out here and locate half a district for his relations who will never see the ground. One consolation is, however, that such claims are not held very long, the expenditures necessary annually cleaning out such non-residents after a year. Still, some harm may be done to actual miners by people holding such ground even for a year, as it might prevent important developments. Some districts, we understand, have laws on the subject, which if they do not conflict with the United States law would, of course, stand. We do not recollect ever having heard of any legal contest on the point in question, so that it might be brought before the courts, but we feel pretty certain there is nothing in the law to prevent the practice, no matter how objectionable it may be.

NEW STEAMER FOR THE HAWAIIAN ISLANDS TRADE.—Williams, Blanchard & Co., agents for the Hawaiian government, have contracted with the Risdon Iron Works for the building of a wooden steam propeller of about 600 tons—the hull and wood work to be constructed by Dickey Brothers, and the machinery, boilers, etc., by the former firm. The contract price of the vessel is \$90,000, which is under what she could be built for at the East. The following will be her principal dimensions: Extreme length, 174 feet; length from rabbet of stem to after side of main stern post, 162 feet 3 inches; beam molded, 26 feet 6 inches; extreme breadth, 27 feet 3 inches; depth of hold to under side of upper deck, 17 feet 3 inches. All timber used in the construction of the vessel (except where otherwise specified) to be of best quality of Puget sound pine. The rig will be that of a fore-and-aft, and she will have a compound surface-condensing engine. The work will be executed under the direct superintendence of Captain Martin Bulger, the efficient superintendent of the Pacific Mail Company. This will be the largest steamer ever built in San Francisco. She will be employed to ply between Hawaiian Islands.

SUTRO TUNNEL.—Measurements taken in the Sutro tunnel, on Friday last, were as follows: Distance made at the header since last measurement, 148 feet; total for the month of January, 388 feet; total length of the tunnel, 15,865 feet. For the week, from the 22d to the 29th, 106 feet were made. The month's work is a very heavy one. The *Enterprise* says that one day last week 15 miners' inches of water were struck. This water was warmer than any heretofore encountered, which would seem to indicate the header to be in the vicinity of some of the eastern fissures of the Comstock. The total flow of water now is about 113 miners' inches.

Twelfth Industrial Exhibition of the Mechanics' Institute.

Steps have already been taken for the twelfth industrial exhibition of the Mechanics' Institute, which is to open on Tuesday, August 7th, 1877, and continue for at least 30 days. The exhibition will be held in the Pavilion on Market, Eighth and Mission streets. The building is 200 feet wide, 550 feet long and 100 feet high, with a gallery around the inside 50 feet wide, besides a promenade 16 feet wide and 1,000 feet in length. In addition to this space, there is a horticultural garden 70 by 220 feet, for the display of fruits and flowers. The "mechanical annex," for the display of special machinery, is 200 by 50 feet.

A large and powerful engine will furnish the motive power for all machinery required to be in motion, while steam and water will be supplied in ample quantities to such machines or appliances as require them. The main line of shafting is 500 feet long, with sufficient pulleys for all requirements.

The art gallery is 400 feet long by 50 feet in width, well lighted by sky-lights during the day and at night by the most improved reflectors. It will be made specially attractive, the directors announcing that many noted works of art are already promised, so that it is confidently expected that this department will excel anything ever before seen on this coast. A grand instrumental concert will be given each afternoon and evening by an orchestra composed of the best musical talent on this coast, and under the leadership of an experienced and popular conductor.

In accordance with the general request of exhibitors, the management have decided to offer liberal premiums at this exhibition, consisting of medals and cash, all to be for the first degree of merit only. The medals will be of a new design, three and a half inches in diameter, and somewhat similar to those awarded at the Centennial exhibition. This idea is a good one, as it promotes a spirit of emulation among exhibitors and encourages them in making their displays as attractive as possible. The miscellaneous diploma system is worn out and we are glad to see that the managers intend giving medals and cash for only one degree of merit, instead of giving everybody something to keep them all in good humor. The proposed method will entail some intelligent work on the part of the committees, but the awards will be more satisfactory on that account.

A carefully prepared classified list of premiums will shortly be published. The circular of the managers states that articles may be entered for competition or exhibition only; but if for the former they must be so designated when placed in position. A copy of the premium list, blank applications for space, rules and regulations and any information regarding the exhibition will promptly be given or sent, by addressing the Secretary of the twelfth industrial exhibition. J. H. Culver, 27 Post street, is the Secretary. The Board of Managers consists of A. S. Hallidie, H. L. Davis, George Spaulding, Asa R. Wells, Daniel E. Hayes, Jeremiah Browning, James Drury, P. B. Cornwall, James Spiers, James C. Patrick, Charles Elliott, Henry S. Smith, J. H. Stoutenborough and J. B. Stetson.

It is important that all parties intending to contribute to this exhibition should give early notice of the amount and kind of space required. Those who intend exhibiting should commence to prepare as soon as possible, so as to have their articles ready for display on the opening day.

A VISIT FROM FRANK LESLIE.—We have the pleasure of first announcing the contemplated visit of Mr. Frank Leslie to California and neighboring States. It is his intention to leave New York in March, with artists and editorial assistants accompanying, and he intends business. By the publication of correct California views and scenes, drawn on the spot, and published broadcast over the world, Mr. Leslie's illustrated journals will do our coast a material benefit, hence our people are all interested in the success of Mr. Leslie's tour among us. We recently visited Mr. Leslie's newspaper establishment in New York, and found it, even in these dull times, a perfect beehive of industry. Seventeen regular publications are edited, composed and printed entirely in the building. The business, drawing and engraving, added to the other departments, makes up an immense concern, all built up with remarkable rapidity, to the credit of Mr. Leslie's dashing enterprise and judgment.

THE suit which was on trial in the District Court, between the Providence mining company, and the Fryer Noble Metal mining company was decided in favor of the plaintiffs. The suit was brought to recover the value of 16 tons of ore sent to the Fryer works for treatment. The judgment of the Court was that defendants pay \$1,523, which, according to our figuring, is at the rate of \$95 and over per ton.—*Nevada Transcript*.

THE Secretary of the Treasury says he has sufficient silver to meet the legitimate demands, and declines to re-exchange United States notes for silver brought to the department in sums varying from \$10 to \$100.

The "Packsaddle."

What a hardy, independent race of men the early backwoods pioneers of America were! The "pioneer" of to-day, as, seated upon his gang-plow, he turns over the loose soil of his San Joaquin valley ranch, while his wife chafers at the gate with the pedlar over the price of the vegetables and fruits she has just bought to furnish forth the family table, can scarcely realize how, 60 or 70 years ago, his grandfather could have spent years hewing and grubbing and burning out the scanty "clearing," from among whose stumps and rocks the old-fashioned single plow was to find sustenance for perhaps half-a-dozen hungry young mouths beside his own, aided by "mother's" hoe in the little vegetable patch behind the cabin. Nor does the settler upon the more rugged lands of Northern California and Oregon, who depends upon the "store" for his clothing, his bacon, his candles, his "canned goods" and a thousand other necessities, and who discusses with his neighbors the expediency of establishing a co-operative store to buy his goods at first hand "down at the bay"—seldom does he reflect that his ancestors in the backwoods of the East prided themselves upon the fact that all they needed they could produce themselves, if need be, and that their visits to town were made but once or twice a year.

Here has been a change indeed. But the chief factor in it is not far to seek; it is the mightiest agent in our modern civilization—the locomotive. Great as is the contrast between the rural life of to-day and of the earlier decades of the present century, it is as nothing when we think of the difference in the means of transit then and now. To-day the emigrant to Colorado or California rattles along over the iron road with the speed of the wind, and in a week's time has left behind him two or three thousand miles and finds himself safely landed, family and household effects, without any real exertion on his part, wherever he may have chosen to settle. Then it was a different matter. The farmer of the Atlantic slope who had resolved to emigrate to the then Great West, whether it be to the smiling banks of the beautiful Ohio, the rich Blue-grass region of Kentucky or the blooming prairies of the Hoosier State, had before him a long, tedious and arduous journey—one that would likely call all his powers of endurance into requisition. If he resolved to wagon it he must see to it that his wheels and whiffletrees were of the stoutest, and be prepared for all sorts of accidents and emergencies upon the rough mountain roads leading from the seaboard across to the valley of the Mississippi. If he chose to go by any of the few water-ways that had been sought out to lighten labor, he must carry with him a good stock of patience, steady nerves, and an arm ever ready to assist in getting over shallow or dangerous places.

The view upon this page, which we have taken from the *Rural Press*, represents a locality somewhat celebrated in those days of primitive travel. It is situated upon what was then, and is now, one of the favorite routes to the central West, being very much the same that is now followed by the Pennsylvania railroad; in those days, however, the iron horse had not yet made his advent, and water was the means of transit. Leaving the valley of the Susquehanna, the traveler journeyed slowly and laboriously up the Juniata—first by keel-boat or canoe, afterwards by canal-boat—until its headwaters were reached. Here there was a portage of 20 or 30 miles across the Allegheny mountain summit to the waters of the Conemaugh, a bright little mountain stream which empties into the Allegheny some 30 miles above the junction of that river with the Ohio. Upon this Conemaugh river is situated the "Packsaddle," represented in our engraving. This was a point where the plucky little river, having forced its way through one of the outlying ranges of the great Allegheny chain, tossed and foamed down through the gorge it had made in a style that forbade all attempts to pass it with any save the lightest of crafts. Keel-boats and, later on, canal-boats, coming either way, were compelled to stop and unload their freight on to the backs of mules or horses, and in this way it was carried on a well-beaten trail over the steep mountains, past the obstruction to the clear water on the other side.

This was the origin of the name "the Packsaddle," which still clings to the locality, though the railroad has long since done away with the old water-travel, and an old-fashioned packsaddle would now be looked on in the neighborhood as a curiosity.

The view will call to the minds of many of our readers similar ones among our own mountains, and probably scenes grander in proportions and more rugged in outline. It would be difficult, however, to find in California, such heavy and varied forest growths and such dense and closely matted underbrush as covers these Pennsylvania hills. The length of the Packsaddle gorge is some six or seven miles; the height of the mountains (Chestnut ridge,) through which the river has forced its way is from 700 to 900 feet above the river, but the sides are exceedingly rough and precipitous, and with the river roaring and foaming over the rocks in its bed below, a picture is formed that has few equals in the East for wildness and picturesque beauty.

Academy of Sciences.

The regular semi-monthly meeting of the California Academy of Sciences was held on Monday evening. L. A. Scowden was elected a resident member.

A communication was read from the Royal Academy of Sciences at Turin, giving the clause of the last will and testament of Dr. Cesare Alessandro Bressa, providing for a biennial

county, noting a mistletoe found on a pear tree, etc., and reporting the discovery of two grave-stones two into six feet, an inch and a half thick; one conical and both bearing raised letters like Egyptian inscriptions. They were found four feet under ground, near Kern lake. Between them was a vase and bones of a human skeleton, with arrows, spear-heads, etc. Mr. Jewell stated that he would inquire a little further into the subterranean mysteries of that locality.

Dr. Stout, Corresponding Secretary, stated that he had advised the discoverer to take casts of the relief letters. He pointed out characteristic differences between the raised letters of the Kern county stones, and those cut into the Egyptian stone itself, and pronounced the Kern discovery the site of an ancient Indian mausoleum.

Dams Across Rivers.

Professor Davidson read the first of his papers on the practical application of his deductions on the irrigation of Asia and Europe. He treated of the location of dams across rivers, and the rules governing such works. He held that a dam should be located on a natural bar if possible, or at least treated like a natural obstruction. It should be located in the broad reaches of the stream, instead of a throat, and be run at right-angles with the direction of the channel. This position was illustrated by numerous examples in India and Italy.

Pacific Coast Meteorology.

Dr. Gibbons proposed the formation of a "meteorological section" in the Academy, thinking it would form an important branch. He

Mechanical Ore Concentration and Separation—No 21.

(Written for the Press by FRANCIS M. F. CAZIN, M. E. Santa Fe, New Mexico.)

Test of the Product of the Successive Sieves by Assay or Microscope.

No one versed in metallurgical matters will doubt the benefit to be derived from assays in all stages of metallurgical operation, whether mechanical or chemical. But the mineral dresser, though bound to be governed by the result of the assay in the different stages of his operation, can derive no benefit therefrom as far as the indication of the course to be pursued by him goes. The lens or microscope has to instruct the mineral dresser more than the chemical test.

It is of the highest importance for the mineral dresser to know, in case the reserve sieves (3, 4 and 5) contain valuable parts, in what shape these parts are: first, whether the metallic particles are still unbroken from the rock; second, whether the metallic particles are broken from the rock, but differ in size so much from the particles of rock that their specific gravity in effect is neutralized by the bigger size of rock particles mined therewith; third, if the metallic particles are in size equal, and are also free from rock, and have gone over only from the first sieves, because their percentage was too high for the capacity of these sieves.

The remedy against loss, or the mode to recover the contents of what the later sieves turned out, will be and must be a different one, accordingly to what the microscope shows. In the first case the ore so showing must be kept separate, and be submitted to further breaking; in the second case, this portion of the ore must be assorted closer according to size; in the third case the feeding only should be slower and the material be fed back, which in the two other cases would only make the result worse instead of better.

If by the operation of any machine or work it is thus established that certain modifications have to be entered into on account of the nature of the ore, no hesitation should stand in the way of doing so at once.

The best constructed establishments, therefore, provide in their construction for certain modifications, as almost certainly will occur with the changes in the ore to be treated, as

stopes, furnishing the ore.

LIDA.—A correspondent writes us from Lida, Esmeralda county, Nevada, that very little is doing there in the way of mining. A half dozen men or so are "chloridizing" in some of the richest old mines and working the ore themselves. They make from three to six dollars per day to the man. The writer thinks the camp will, some time in the future, come from under the cloud which has been hanging over it for the past few years and make a showing equal to any of the neighboring camps which are now turning out their thousands per day. The mines are there and also any amount of timber and water enough to run all the mills that need to be built to work the ore.

In the Senate on Saturday, Hamlin offered an amendment to the Postoffice Appropriation bill appropriating \$500,000 for steamship mail service between San Francisco and China and Japan for one year, and authorizing a contract with the Pacific Mail Steamship Company for transporting a monthly mail between the ports designated.

THE *North German Gazette* reverts to the anti-German articles in the *Revue des Deux Mondes*, and says: These expressions are significant in France, because a renewal of war against Germany is considered by every one only a question of time and constitutes a permanent factor in all political calculations.

The Southern Pacific Railroad Company has already laid its track to a point 20 miles east of Indian Wells, and is extending it beyond at the rate of two miles per day. Two thousand men are employed in grading, etc., and it is sanguinely anticipated that the road will be completed to Fort Yuma before March 15th, next.

THE "PACKSADDLE," CONEMAUGH RIVER, PENNSYLVANIA.

prize for the best scientific literary production.

Abnormal Formation of Deer's Horns.

Dr. Kellogg read an interesting paper on further evidences of a curious law of abnormality in the horns of deer. The facts had been brought to his notice through a collection of horns reported by Joseph Clark, of Mendocino county. These facts were considered worthy of record, chiefly for the sake of future confirmation by zoologists. It had been observed that in each instance of abnormal growth, the animal taken had been in some way maimed; and the law was thence reduced to the following definition: "Any particular injury to the animal, such as the loss of an eye, lameness, or the loss of a leg, or a simple wound of the side, more or less grave, is always ultimately recorded in the deviation of the horn on that side of the head from its normal symmetry. In cases of general injury, both horns become greatly distorted and strangely abortive, like a mass of coralline growth, and at length the male deer becomes altogether hornless." Common observation showed that the characteristic form of the horn, as shape, symmetry, size, power, etc., was the resultant product of the animal, and therefore duly and truly represented the animal itself. This law extended to all horned animals. The mysterious monstrosities were supposed to bear a subtle relation to the wonderful sensitiveness and marvellously rapid growth of deer's horns, but the philosophical speculation of the subject was reserved for future papers.

Dr. Kellogg also presented a new species of spruce, discovered by George W. Dunn, in some of the passes of Arizona, locality not reported, and read a paper on a new species of *Listera*, discovered by Dr. G. Eisen, in the Kings river section of the Sierra Nevada mountains.

Indian Relics from Kern.

A letter was read from S. W. Jewell, of Kern

stated that the Signal Service in Washington desired to open communication with a society in this line on this coast, and if those interested would join and form the section, benefit would result. Mr. Scapham stated that the Central Pacific railroad had fifty signal stations, from the Rocky mountains to the Gulf of California, and that the observations had been full, reliable and of considerable use, and regularly reported to the Smithsonian Institute at Washington. He had no doubt that their data would be reported to the meteorological section of the Academy also, if desired. The President said that a number of gentlemen of this city proposed to establish a number of meteorological stations on the northern coast, between here and Alaska. The Government itself is about to establish a tidal station at some point on the Alaskan coast. This subject is one of great importance to the agricultural and mining interests of the coast.

The twenty-fourth of a series of papers on Pacific coast *Lepidoptera* by Henry Edwards was filed for publication. This series is a very valuable one to entomologists, and Mr. Edwards, who is a patient and persistent worker in this line, has gleaned very many new and interesting facts in his researches.

At the annual meeting of the Sheffield Chamber of Commerce on Saturday, the President said Sheffield manufacturers and workmen had only themselves to blame for the loss of trade with America, and successful American competition with foreign countries. Sheffield workmen had not come up to the make and style required by their customers.

The legislative appropriation bill as passed by the House on Saturday reduces the President's salary from \$50,000 to \$25,000, and fixes the annual salary of Senators and Representatives at \$5,000.

THE ENGINEER.

Chemistry Applied to Engineering.

At the meeting of the English Civil and Mechanical Engineers' Society, a paper was read by Mr. Bernard Dyer, F. C. S., on the subject of "Chemical Analysis Considered in its Application to Civil and Mechanical Engineering." Mr. Dyer's paper opened with some remarks on the close connection of chemistry with other sciences, drawing attention to the marked and subtle relations between the chemical composition and physical properties of various kinds of matter. The influence of minute proportions of certain foreign substances, such as phosphorus and sulphur, upon the quality of iron and steel, was alluded to under this head, as also were the variations in the electric conductivity of copper wire designed for telegraphic purposes when certain impurities chanced to be present even in minute traces. The composition and properties of some of the principal alloys of copper having been briefly referred to, the value of chemical science in studying the nature of furnace action, with the view to the economy both of heat and fuel, was considered, the desirability of systematic chemical analysis of the coal or coke used in most metallurgical operations being also pointed out. The subject of furnaces led to some observations on the nature of fire-clay and other refractory materials, the author showing that while, for all practical purposes, chemical analysis should decide upon the suitability or otherwise of a given clay for use in a high temperature, there was still room for sound chemical research in discovering the best artificial substitutes for natural fire-clay.

The subject of water analysis was treated at some length, both as regarded the supply of drinking water and the suitability of various waters for boiler use, some practical remarks being introduced on the occurrence and prevention of boiler incrustations. The distinction between "hard" and "soft" waters, and the softening of the former under treatment by Clark's process, were described, the author quoting a recent statement by a well known engineer, to the effect that no less a sum than £50,000 is annually lost to the people of England by the wasteful consumption of soap entailed by the use of hard waters. The London water supply if treated by Clark's process would probably deposit upwards of 50 tons of chalk daily. The subject of oils and other lubricants, with reference to their adulteration with drying oils and the consequent damage to machinery, having been alluded to, the paper was brought to close with a passing reference to sewage purification, agricultural chemistry as affected by engineering, and gas, matters into which the author regretted that the limits of space and time at his command forbade him to enter further.

A discussion followed, in the course of which it was suggested that chemistry might be applied with advantage to the art of building, in order that edifices might no longer be constructed in London of stone which crumbled under the atmospheric influences to which it was exposed. General agreement was expressed that the analysis of samples of material was very important, as tending to insure greater uniformity of quality in manufactured articles used in engineering, and supplied by contract, though, with regard to steel rails, it was pointed out that there was great difficulty in obtaining anything like a uniform quality of product, the same bar often furnishing different results if analyses were made of two or more parts of it. Mr. Dyer replied, observing that he did not think chemical analysis could be expected to throw much light on the nature of wood with regard to building, or, in all cases, the durability of stone; but he thought microscopic examination of the first named material might possibly be found useful if carefully studied; and as to stone, the softest chalk and the hardest marble, for example, were chemically the same substance.

Changing the Course of the Danube.

To avoid the rocks by which the navigation of the Danube has for ages been obstructed at the point known as the "Iron Gates," a new bed has been prepared for the river, of which the Danube has taken possession for itself without waiting for any opening ceremony. This river was dug out in three sections, separated from each other by two dykes, which were left, and over which the roads led to the old bed. The embankment has been raised all along the line and reveted with stone. It was determined to make an opening in the upper dyke so as to allow the stone barges to pass through. Scarcely was the channel opened when the stream rushed in, widening the gap soon from 12 feet to 100, carrying away the bridge which had been constructed. The dyke being in an oblique direction, the gap was made toward the right bank, the consequence being that the force of the stream rushed in that direction, carrying away the masonry and stone pavement for a considerable distance. In less than 12 hours the basin filled. Curiously enough, the difference in the level of the old channel is found to be not near so great as might have been expected, 18 inches being registered as the fall, and for the present there are two streams, the old one not having been as yet stopped. The new channel is nearly nine and one-half miles long, and brings the water of the Danube with-

in a short distance of Vienna. It consists of two parts: The minor channel, which, in ordinary times, will receive all the waters of the river, is 245 meters wide and three to 3.50 meters deep; the other, which is to provide against floods, is 515 meters wide and two meters deep, with a dam 6.32 meters high. Sixteen millions of cubic meters had to be excavated for raising the level of the soil and forming the dam, and half of this by dredging; the stone work of the new dams represented a cube of 350,000 meters, and the pitching nearly as much. The quays absorbed 35,000 cubic meters of concrete and 30,000 meters of masonry.

Engineering Items.

THE Government authorities are still at work on the jetties for the protection of the beach in front of the lighthouse at Atlantic City.

THE Hell Gate improvement has not yet been of any benefit to New York shipping. The officers in charge complain of want of funds to complete the works.

THE latest important engineering work is the Bergen hill tunnel, New Jersey, on the line of the Delaware, Lackawanna & Western railroad. It was begun three years ago, and gave employment to a force of about 600 men. It is nearly a mile long, 27 feet wide and 18 feet high. Two tracks will be laid through it.

THE Suez canal is looked upon as a success by European capitalists. This water-cut, connecting the Mediterranean and the Red seas, is at present patronized by 24 regular lines of steamers, employing 234 steamers, of 509,437 tonnage. Classified by nationalities, the quota of England is 152 vessels, of 390,273 tonnage; France, 18 vessels, of 112,624 tonnage; Holland, 15 vessels, of 36,585 tonnage; Austria, 18 steamers, of 28,227 tonnage; Italy, 10 steamers, of 15,518 tonnage; Russia, 8 steamers, of 13,386 tonnage; Germany, 8 steamers, of 11,336 tonnage; Spain, 5 vessels, of 10,751 tonnage.

A WRITER in the *Polytechnic Review* on "Style in Engineering Constructions," says: "Style may be defined as the principle of form, both in architecture and in engineering structures. Architecture growing up simultaneously with history, has been influenced quite as much by the political, religious and artistic tendencies of nations and races, by local, social and climatical conditions, as by the materials at their disposition, their knowledge of mechanical and physical laws, and their tools and skill in using them. Engineering, in the present age of quick intercommunication and widely diffused knowledge, is more cosmopolitan, and thus mainly under the influence of the last named conditions. To adapt our structures to the objects in view, to give them sufficient strength, and to do this with the least expenditure of material and work, must always be the first and paramount consideration. To combine with this pleasing and graceful outlines, to study the details carefully, so as to obtain uniformity of the whole, ought to be the aim of every constructor, and within these bounds he has certainly a wide range, either to be led on by his own fancy, or to follow, without copying slavishly, the examples that have already established certain principles of form for the different branches of engineering.

THE EAST RIVER BRIDGE CABLES.—The Board of Trustees of the New York and Brooklyn bridge, says the *Iron Age*, have decided that crucible steel must be employed as a material for the wires from which the cables of that structure are to be spun. The Executive Committee reported that in consequence of the strong vote of the board in favor of awarding the contract for the wire for the large cables to the lowest bidder for crucible cast steel as decisive against the use of Bessemer steel, for so important a matter as the main cables, it would, in their opinion, be unwise to adopt a material which is distrusted by any considerable portion of the trustees. The question of cost is an important one, but is subordinate to that of safety, and the difference of expense between the two is comparatively too small to permit such difference to prevent unanimity and entire confidence. They therefore, recommend that the contract for the steel wire for the large cables, as provided in the specification issued for that purpose, be awarded to J. Lloyd Haigh at 8 7/10 cents, gold, per pound, he being the lowest bidder for crucible cast steel wire, provided he furnish that kind of wire stipulated in his communication to this board, dated January 9th, 1877.

A DAM.—The following is a description of a dam recently constructed across the Kansas river, at Lawrence, and which has been estimated to furnish about 3,000-horse power: The dam is 788 feet in total length, 274 feet of which is based upon solid rock and built of masonry. The remainder spans a gravel and sand foundation, and is constructed of crib work, thoroughly based, anchored, grouted and backed. The dam has a base of 21 feet, presents an average angle of 45° to the current, and is so constructed that the power can easily be increased by adding to its height. The flume upon the south side is 60 feet wide, and, as it now stands, 180 feet long, and is simply supplied with arches for the convenient delivery of power to penstocks. The track of the Kansas Midland railroad, connecting the Atchison, Topeka & Santa Fe railroad with the Kansas City railroad system, runs within a few feet of the flume walls.

The Battle Creek Mines in the Black Hills.

A correspondent of the *Eureka Sentinel* writes from "camp on Battle Creek" as follows: One has hardly time to locate himself comfortably here until the report comes that still better "diggings" have been found, and away we go with our blankets, grub and cooking utensils on our back or a pack animal. The latest excitement is Battle Creek, and a general stampede followed the first rumor. The diggings are nearly north of Custer City, about 30 miles from that place, in the foothills of a low range of mountains that until recently the prospector would not idle his time away examining. Battle Creek is about 20 miles in length and reported to be very rich from one end to the other. The bedrock has not been reached but in few places, and will lay at an average depth of 20 feet. The discoveries thus far are what are known as placers and will make a good showing. One nugget taken out three weeks ago by Captain Timblin

Weighted Over Fifteen Dollars.

And lots of others have been since found, and many of greater value. A pan of dirt taken from the same locality washed out \$10. When it is understood that four and five cents per pan is considered good pay in ordinary diggings, the value of this claim, which is owned by a French company, may be readily estimated. Gardner & Turner's men washed seven loads of surface dirt from their dry gulch claim one day last week, and realized \$35 in three hours. The firm is now building a ditch 1,200 feet long, preparatory to working the claim on a larger scale in the spring. There are about 60 men working on the creek at present, and as many more upon dry diggings, while an army of prospectors are scouring the adjacent country.

Mining affairs in this vicinity are becoming interesting, to say the least, and the present outlook is such as to reaffirm the assurance given a year ago, that Custer is destined to be "the metropolis of the hills." Its advantages over all rivals in being 75 to 100 miles nearer railroad facilities (no mean consideration in these days of high freight tariff) and its delightful and healthful location are important

Points in its Favor.

In addition, there have been quartz leads discovered, which, if they come up to assayed samples, eclipse anything yet reported in the hills, and equalled by few anywhere. The principle leads are the "Centennial," "De Smett," and "Webfoot." The last named is the richest—claim No. 2 (second from discovery) assaying \$36,000 to the ton, the samples being taken at a depth of 8 feet from the surface. Claim No. 8 is said to be still more valuable—the vein producing almost a solid mass of gold. The lead commences near the city and runs due north. The principal claims are held by a company of Eastern capitalists, who will have a stamp mill here in time to begin work early in the spring.

Custer is almost deserted. The miners have either gone home for the winter or else joined in the stampede to Battle Creek. Vacant houses outnumber by far those occupied, and but little business is transacted. The few who remain, and the merchants, are, as a class, far above the average quality of men to be found in mining camps. There are no dance houses or gambling institutions in the place, and the utmost order prevails.

The Nevada Bullion Tax.

An important joint meeting of the Finance committees of the two Houses of the Legislature was held at Carson yesterday, at which there were present representatives of the leading mining interests of the Comstock. The bonanza companies were represented by Superintendent J. G. Fair; the Belcher by Superintendent W. H. Smith; the Yellow Jacket by Captain Taylor; C. J. Hillyer and W. S. Wood, attorneys, were also present, with representatives of other leading companies. The object of the meeting was to consider the bullion tax. The discussion was informal, but full, free and pleasant. The mining men found no difficulty in getting their views before the committees, with whose intelligence, earnestness and candor they were highly impressed. The immense amount of capital represented at this conference pays more than half the tax of the State, and is therefore entitled to all the courtesy and consideration accorded it. The mining interests do not ask a repeal of the bullion tax, nor any release from the payment of their fair and equitable proportion of the tax required for the support of the State Government. But what they did ask, and what they sought most earnestly to impress upon the committee is, that their property should be taxed precisely as other property is taxed. Real estate, merchandise and other property subject to taxation is assessed at an easy valuation, usually arrived at by guess work, never sworn to, and rarely at anything like its actual value; whereas the mining companies are required to make return under oath of every ounce of bullion, which is assessed at its full value, and the tax is rigidly collected. The mining companies are willing to pay their tax on this basis, provided all other taxable property is treated with the same severe exactness. Such a course, they think, would greatly increase the general assessments, and so materially reduce the rate per cent. of tax on all. They also showed to the committee as another instance of the present law's injustice to them, that they are required to pay their tax monthly, while no other taxes are collected

but once a year. They protest against this discrimination as unfair and unjust. Of course the result of the conference cannot be known until the committees report to their respective houses.—*Virginia Chronicle*, January 27th.

Home Encouragement for Mining.

The following from the *Nevada Transcript* contains many good points: While we have any quantity of quartz ledges, and large fields of unworked gravel claims, and while every one here knows that the prosperity of the county depends upon their opening and development, yet there is but little local encouragement to outsiders to come here and invest. It is an even bet that if 10 men succeed in inducing capitalists to come here on a trip of inspection, with a view to investment, that there will be at least one man, if not a dozen, in the community, who will undo all the 10 have accomplished, with the least imaginable effort. Hardly a mine has been opened in this vicinity by strangers, but has to be worked in opposition to the croakers or smart Alecks. Even the Providence owners, after they had expended over \$25,000, were visited by a committee, who told them there was nothing in their mine and never would be. Capitalists on attempting to open new claims here, find another difficulty, which is a worse curse to the county, even, than the predictions of the impetuous smarties who use their tongues only. No matter where developments are commenced on new ground, they will not proceed far before adverse claimants will appear, and an expensive lawsuit will have to be engaged in before a title can be secured, and the chances of winning a suit against such claimants are very doubtful.

It is almost impossible to prove abandonment of a mine in our courts, even if a claim has laid idle for years, and is generally understood to be abandoned and worthless. All such original claims are generally held by poor men who have not been able to open them, and are waiting for something to turn up. It is probable that nine-tenths of such claims never will be touched after those are driven off who are willing to spend money to prospect them. We don't want to find fault with men for desiring to hold a mining claim, when they do so under the law and with a view of future development, but we do think it their duty to notify all who commence to work on their claims before they expend money and time, that the ground is claimed and will be defended. It is a fact that these possessory claims held by those who intend to do no work further than to barely comply with the existing law, are a damage and a ruin to the county. When a few men who are willing to invest means to open new industries are prevented by such claimants, there will be little inducement for others to try, and the result will be just what we now complain of, viz: A vast area of country with boundless resources, but no development and consequently no general prosperity.

Shipping Ores from Idaho.

The bill introduced in the council by R. A. Sidebotham, levying a tax on all ores shipped from this Territory for reduction has created great excitement among the people of Alturas. These Eastern companies, who never work for the interest of the country or the people at large, are bitterly opposed to this measure, simply because they do not wish to go to the expense of bringing in machinery to work the ore here. I want to see that bill passed and be made a law, and so does every working man in this county. If it becomes a law, then they will be compelled to bring in the proper machinery to reduce the ore at home. If it is defeated, these Eastern monopolies will continue to send all the money out of the country as long as it is in their power to do so. There have been several letters written from this camp, and every one is opposed to this measure, because they are owned by these companies. Laying all pledges aside, let every man in that legislative body support that measure. Then this camp will boom up and equal Virginia City. We have the mines; all we want is the right kind of men to develop them. Since my last, there have been three new strikes made. Wm. Irwin & Co., of the Moultrie, have struck an eight-inch vein of ruby silver. Simon Taylor, who has been running a tunnel for the extension of the Last Chance, tapped the ledge a few days ago. It is fully as rich, if not richer, than the original. Andrew Johnson & Co. have struck it rich in the Little Buffalo.—*Cor. Idaho World*.

MANHATTAN MINE.—A drift has been started to run east from the 577-foot winze under the large chimney the winze is in. This drift, as well as the one running west, carries a very large ledge of magnificent ore. A contract was let last week to extend the 600 east Panamint drift of the Bowman incline, and a large ledge was encountered containing \$200 to \$400 ore. This ledge is about 300 feet east of the chimney now being worked in the Curtis shaft and is an entirely new development.

THE board of managers of the Mechanics' Institute announce that the twelfth annual industrial exhibition will be opened on Tuesday, August 7th, and continue open for at least 30 days.

The Eureka Lake Water and Mining Company.

From a recent report of James D. Hague, the Nevada Transcript reproduces the following interesting items in regard to the property of the Eureka Lake water and mining company, situated on the San Juan ridge. The water improvements comprise over 200 miles of ditches, several large storage reservoirs and a series of distributing reservoirs. They cost in construction over a million dollars. The average possible delivery is stated at 2,000,000 inches a day, of 24 hours each, annually. The average price paid by purchasers of the water is 20 cents per inch per 24 hours. The average cost of operating the water property is about \$85,000 per annum. Part of the water is used by the company in running its own property. The average yearly receipts during 11 years past from the sale of water have been \$180,782. The mining ground owned by the company lies at several points along the ridge, mainly at Columbia Hill and Bloomfield. The Columbia Hill property comprises a body of ground two and a half miles in extent, all located on the ancient river channel. The deposit is estimated to contain \$18,000,000, the larger portion of which lies in the ground too low to be mined without long tunnels from the river. It is now being worked on a large scale. Last year's products from it amounted to \$120,803, at a cost of \$35,965 for other things than water, which was from the company's own supply. It is expected that the yield this year will be \$240,000, at an expense other than water of \$75,000. This can be carried on for 10 or 12 years with the present outlet. The water sales and proceeds of the Columbia Hill mine will produce an annual amount of available yearly profits—allowing 25% for contingent expenses not now contemplated—of \$150,000, or \$200,000 if the contingencies do not arise. The Bloomfield ground adjoins the North Bloomfield hydraulic mine on the south, and on the same channel. This can be opened by a tunnel 4,000 feet in length. There are 720 acres in the tract, and it is expected to be as rich as the ground of the North Bloomfield company on the north. The supply of water is lasting and the demand will continue as long as there is unworked ground along 20 miles of the line of the old channel, which is as yet hardly touched. The company also own rich claims at Relief Hill, Moore's and Woolsey's flats and Snow Point. The property is one of the most valuable in the State, and is capable of almost unlimited development. Marks Zellerbach is the principal owner. The property is ably superintended by K. McMurray, of San Juan.

FISH SPAWN FROM THE EAST.—A few weeks ago 300,000 whitefish spawn were sent to this coast from Lake Michigan by Professor Baird, of the United States Fish Commission, for shipment abroad. Of the consignment 150,000 spawn were shipped to New Zealand, 30,000 to Japan, and the balance reserved for California and sent to the hatching establishments near Berkeley. One hundred thousand of the last mentioned were successfully hatched and placed in Lakes Donner and Tahoe. One hundred thousand eggs of the speckled trout were also received at the same time from New Hampshire, and of the lot 60,000 have been successfully hatched. There is another large consignment now in the office of Wells, Fargo & Co.'s express destined for Australia. They are said to be in very poor condition, owing to the sudden change of climate.

The Olin concentrators are partially in operation, the hand jigs being worked and running upon a lot of 60 tons of second-class ore taken from the Mountain lode. On Friday last Mr. Olin received from Helena the long delayed and anxiously expected belting and castings, which have heretofore prevented his starting the automatic jigs, and now with everything requisite at hand there is no reason why these works should not within a few days be put in full operation at concentrating the low grade ores of this camp.—*Butte (Montana) Miner.*

SAYS THE PETALUMA ARGUS: Moore Brothers this week sold to Milton S. Latham their entire interest in the North Pacific Coast railroad, together with their saw-mill property and timber land situated near Moscow, the present terminus of the road. It is stated that Mr. Latham will immediately commence the construction of a new mill at Willow Gulch, about four miles from Moscow, which will be completed within three months, and will be one of the largest saw-mills on the coast.

CONDOR MILL LEASED.—The Alps mining company, so we learn from Theo. A. Hale, has leased the Condor mill in Condor canyon for six months. That company has also purchased the tailings and concentrations at that mill from W. F. Griffin. The Condor mill is to run in conjunction with the Alps mill. The report that was circulated in regard to stopping of the Alps mill in consequence of the company having leased the Condor, is without foundation, as both mills will be kept going.—*Pioche Record.*

ALPS MINE.—Good progress has been made in the upraise on the 204-foot level, the raise being 30 feet from the top of the drift, the streak of ore continuing all the way. Ore also continues in the winze now being sunk and the prospect is very encouraging. The mill has been running steadily on chlorider's ore, and plenty will be taken out of the mine to insure a constant run until spring.—*Pioche Record.*

Richmond Assay Office.

The building that has for years past been used at the Richmond smelting works for an assay office has proved, with the continued increase of business, entirely inadequate to the requirements of a first-class office, and a new assay department has been fitted up in the stone building, which is also occupied by the private offices. The new assay rooms are three in number, and called the melting, sample, and balance apartments. Each room is supplied with all the latest appliances necessary for conducting the business, and samples of all ores brought to the furnaces for reduction are carefully assayed and the proportion and value of all the different precious metals contained therein minutely ascertained. The scales used in weighing are marvels of mechanical skill. The largest used for weighing the dore bars produced at the works has been lately received from the West, and are the same as those used at the agency of the Bank of California at Virginia City. It is a standard balance, manufactured in Boston and cost originally \$3,000. With this is found the exact weight of the bars of bullion made at the place, and so perfect is its adjustment that the weight of the finest hair can be readily ascertained. Another balance scale is of so delicate construction that it is kept inclosed within a glass case. This is used in weighing the small particles of silver and other metals obtained from samples of the ores assayed. In the melting room a fine furnace has been constructed, and by a simple method is kept free from dust. Mr. Davis, the competent assayer employed by the company, has now a very convenient office in which to carry out his work, and he and his assistant, Orrin Miller, are much pleased with their new quarters.—*Eureka Sentinel.*

Second Bridge between New York and Brooklyn.

The projectors of this proposed bridge over the East river, between New York and Brooklyn at 77th street, by way of Blackwell's island, have, says the *Scientific American* in response to the invitation sent out, received ten separate designs and estimates from as many engineers. Ground will be broken as soon as a plan shall be decided upon. The preliminary specifications call for an approach on the New York side of 4,580 feet, 1,000 feet of which is to be in form of a tunnel extending from Fourth to Lexington avenues. From the end of the tunnel, an iron superstructure, curving to the center of the blocks between 76th and 77th streets, and thence direct, leads to the river. From the pier on the brink of the river, Blackwell's island will be reached by a single span of 734 feet. An iron structure 700 feet long will then lead over Blackwell's island, and the channel between the island and the Long island shore will be spanned by a single arch of 618 feet. The shore approach on the Long island side will be 3,900 feet in length. This will give in all a total length of 10,532 feet, or nearly two miles. A single track tramway will run across the bridge. There will be, in addition to the main approaches, two auxiliary ones, one from Avenue A on the New York side and the other from Vernon avenue, Long Island City. The spans are to be 135 feet above mean tide water. Double passenger elevators are to be placed at the piers on each side.

Mining and Scientific Press.

Is the leading mining journal in America, and enjoys a large circulation among the more intelligent operators and workers in the gold fields of the world.

As a scientific and mechanical representative of the Pacific Coast, it is decidedly popular and a standard journal with the most thrifty industrial people of the Pacific States and Territories. Its authority is of the highest, order, and its usefulness in its special sphere unrivaled.

Every public library, mining engineer, metallurgist, mining operator and intelligent mechanic and manufacturer will find profit by its reading.

Subscription, \$4 a year in advance. Sample copies, post paid, 10 cents. As an

ADVERTISING

Medium for the Pacific Coast, it is superior to any other journal for all kinds of mining and hydraulic machinery and other mechanical work, building materials, new manufactures and inventions. Our rates are very reasonable compared with those of other first-class journals.

DEWEY & CO., Publishers.

APPRECIATION ABROAD.—We copy the following from the *Mining and Monetary Gazette*, of London, England: "We deemed it advisable, as affording valuable information to our readers, to publish in recent issues of *The Gazette*, the full text of the 'United States Mining Laws and Instructions, by the Commissioner of General Land Office,' taken from our talented contemporary, *The Mining and Scientific Press*, of San Francisco. The documents have now been issued in a handsomely bound volume by Messrs. Dewey & Co., the publishers of our transatlantic contemporary, and it will be found very useful to those already interested in American mines, and to others who may be tempted to embark in that enterprise in the States."

CAMPO, SAN DIEGO CO., CAL., July 3d, 1874.
Messrs. Dewey & Co.—Gentlemen: To-day I received the patent and other papers of my animal trap, that you so successfully worked through the patent office for me, for which please accept my best wishes. The chances are that I will have another application for you to make for me before long. I am well satisfied with your manner of doing business, and I think inventor of this coast stand in their own light when they do not put their business into your hands. I remain yours truly,
A. M. GASS.

Contents of Pamphlet on Public Lands of California, U. S. Land Laws, Map of California and Nevada, Etc.

Map of California and Nevada; The Public Lands; The Land Districts; Table of Rainfall in California; Counties and Their Products; Statistics of the State at Large.

Instructions of the U. S. Land Commissioners.—Different Classes of Public Lands; How Lands may be Acquired; Fees of Land Office at Location; Agricultural College Scrip; Pre-emption; Extending the Homestead Privilege; But One Homestead Allowed; Proof of Actual Settlement Necessary; Adjoining Farm Homesteads; Lands for Soldiers and Sailors; Lands for Indians; Fees of Land Office and Commissioners; Laws to Promote Timber Culture; Concerning Appeals; Returns of the Register and Receiver; Concerning Mining Claims; Second Pre-emption Benefit.

Abstract From the U. S. Statutes.—The Law Concerning Pre-emption; Concerning Homesteads; Amended Act Concerning Timber; Miscellaneous Provisions; Additional Surveys of Land for Pre-emption, List of California Post Offices.

Published and sold by DEWEY & CO., S. F.

PASO ROBLES, CAL., October 18th, 1875.

Dewey & Co.—Gents:—The letters patent for the Tire Upsetter have come to hand. For the prompt manner with which you have brought the matter to a successful issue, please accept my thanks. Yours respectfully,
JOHN H. MERTZ.

THE EXPLORERS', MINERS' AND METALLURGISTS' COMPANION.—Comprising a practical exposition of the various departments of exploration, mining, engineering, assaying and metallurgy; containing 672 pages and 83 engravings. By J. S. Phillips, M. E. Price—cloth, \$10.50; in leather, \$12; postage 50 cents. Sold at this office.

Continued from page 85.

week goes as high as \$2,500 to the ton. There is said to be abundance of it in sight. There is no change to report in the status and prospects of the mines at South Mountain. Only a small force of men is employed there as yet, but there is a generally hopeful feeling that times will brighten up as the spring months approach. At the Belle Peak mine, near Fairview, there are some 20 men employed, who are taking out rich rock, which is improving in quality as the development progresses. The Potosi is looking well. There are over 100 tons of rock on the dump ready for crushing.

A GOOD MONTH.—January was a lively month among the miners. The proprietor of the Rocky Mountain mill informs us that they had a livelier trade in ore during the past month than for many weeks, and we presume such has been the experience of other purchasers.

DUNKIRK.—This well known mine, east of the Dives, the property of the Hermann mining company of New York, is now being operated by a force of 10 men. Sinking the main shaft is going on day and night. The shaft is now over 400 feet deep, and at the bottom there is a fine crevice with a good deal of scattered ore through it. The engine on this mine has a hoisting capacity for 1,000 feet.

DOWNIEVILLE.—The developments on Red Elephant mountain, and in other localities in Downieville district this season, have been such as to attract considerable attention to the mines of that locality, which have been too long lying idle. In addition to the active work now going on, with most satisfactory results, we understand that the prospector is abroad there now, with his pick and shovel, and we may soon expect to hear of other strikes.

Utah.

DRY CANYON.—Cor. Salt Lake Tribune, Jan. 31: In view of the numerous and extensive rich ore strikes daily being made in this camp, among which the one recently made in the Kearsarge is not the least, everybody seems to entertain a kindlier feeling toward his fellow man, being convinced that next summer will bring capitalists in our midst who can and will purchase mining prospects, those which, with a reasonable expenditure of money, will develop into dividend paying mines. There are at least a score of undeveloped mining claims to-day in this immediate vicinity that give every evidence of eventually proving as rich and inexhaustible in ore deposits as are the Mono, Deseret, Kearsarge, Queen of the Hills, Hidden Treasure and others in this canyon.

MINE.—The mines in this district are being worked with a will and they are continually improving. The character and value of the ores found at a depth of from 50 to 200 feet and over, improve very much. A number of miners are engaged in "chloriding," and they have so far met with success in a financial way. The only drawback that is felt by the miners and chloriders is the want of a custom mill in which they can have their first, second and third class ores worked. The Leeds company's mine is raising ore now, and have about 300 tons of first and second-class ore on their dump, which they have commenced to haul to the mill for reduction. The mill is inclosed and the batteries are expected to commence their work on Monday or Tuesday at farthest. The Tecumseh and Silver Flat mines are the great chloriding, and have been the richest paying mines. They have shipped a large amount of value rich ore to Salt Lake City, and hope for reduction, which has yielded its owners a very handsome dividend. The Barbee & Walker is sinking an incline shaft, which is now down 150 feet, the vein pitching at an average angle of 38 degrees, showing ore all the way down. The vein starts on the top two feet wide, and is not less than 14 feet wide at the bottom, showing no hanging or foot wall. The ore will go from \$20 to \$250 per ton.

Meetings and Elections.

WELLS, FARGO & CO.'S EXPRESS CO.—Feb. 5th. Directors—Lloyd Tevis, W. G. Fargo, A. H. Barney, Charles Crocker, Leland Stanford, D. O. Mills, Oliver Eldridge, Mark Hopkins and J. B. Haggis.

CALIFORNIA POWDER WORKS.—Feb. 5th. Trustees—J. H. Baird, N. C. Kittle, J. B. Haggis, J. O. Earl, G. F. Lawton. The Trustees elected J. B. Baird, President; N. C. Kittle, Vice-President; J. F. Lohse, Secretary and Treasurer; B. Peyton, Superintendent.

ATLANTIC GIANT POWDER CO.—Feb. 5th. Trustees—A. Dibblee, President; E. Judson, H. Brickwedel, F. Oppenheim, L. Stevens, H. Pichor, Secretary.

METALLIC CO.—Feb. 6th. Trustees—Geo. S. Dodge, A. W. Rose, S. Reinhardt, S. Heydenfeldt and Jeremiah Miller.

PACIFIC ROLLING MILLS.—Feb. 7th. Trustees—William Alvord, Louis McLane, D. O. Mills, L. B. Benchley and B. P. Bruner. At a subsequent meeting of the Trustees, the following officers were elected: William Alvord, President; L. B. Benchley, General Manager; B. P. Bruner, Vice-President and Superintendent; P. Noble, Assistant Superintendent and Samuel L. C. Sweeney, Secretary.

HENRY A. GOULD has been elected Assistant Secretary of the Nevada Stock Exchange.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's office at San Francisco.

ARCTIC COMMERCIAL CO.—Feb. 6th: Object, catching, preparing, canning, smoking and salting of salmon, cod and other fishes, and trading in furs, provisions and dry goods, establishing trading posts, and carrying on a general commercial and manufacturing business in the Territory of Alaska. Capital stock, \$2,000,000. Directors—David Halliday, George R. Rosseter, Edward Cummings, F. G. E. Tittle and Jacob Shew.

GOLDEN WEST G. M. CO.—Feb. 6th: Location, Yuba Co., Cal. Capital stock, \$3,000,000. Directors—Jas. M. Jackson, Eugene Bradbury, Chas. H. Howland, A. J. Snyder and W. Benetick.

DUNSMUIR LAND AND LUMBER CO.—Feb. 6th: Object, to build vessels and buy and sell timber land. Capital stock, \$3,000,000. Directors, Alexander Duncan, Samuel M. Duncan, J. F. Byxbee, R. G. Byxbee and W. J. Dutton.

LOTTA G. M. CO.—Feb. 6th: Location, California. Capital stock, \$4,200,000. Directors—John F. Snow, E. P. Hutchins, J. C. Yale, G. W. Thomas, C. J. Holmes, J. G. Mather and G. W. Osborn.

AN ENTHUSIASTIC EXPLORER.—Commander Cheyne, of the English navy, in a recent lecture on Arctic exploration, said that rather than see another nation snatch from his country the laurels crowning the discovery of the north pole, he would be prepared to command a private expedition, drive the ship or ships as far north as possible by one of the channels west of Smith's sound, and, failing ability for pushing the vessels within sledging distance across the pole, en route to England via Spitzbergen, he would lead a forlorn hope in a balloon, with orders left to the commanding officer that, in the event of the balloon party not reappearing by a certain date, he should leave the aeronauts to their own resources, and carry on further discovery irrespective of their course of action. If necessary, he would risk two or three lives for the attainment of an object so desirable in the interests of English maritime supremacy.

WM. HOSKINS, a miner working in the Crown Point mine, was killed by being caught in the giraffe on Tuesday.

Notes on a Bruckner Roasting Cylinder.

[Written for the MINING AND SCIENTIFIC PRESS.]

Owing to want of room, and other reasons, the driving gear was placed in reverse position, that is to say, at that end of the cylinder which is next to the fire-box. As the toothed rack on the cylinder could not easily be moved, it was allowed to remain where it was, consequently the longitudinal shaft passed across the ore-pit, under the discharge ports, and the hot ore fell upon it during the discharge, which, however, caused no inconvenience.

To accommodate the transverse shaft, and the gearing in their new position, it was necessary to shorten the ash-pit at the bottom, and build its front wall so as to overhang the gearing, and thus furnish the required base for the iron fire-box.

The only defect developed by this arrangement was, that the overhang finally (after several months,) caused a crack in the side wall and threatened to fall upon the gearing, which, however, can easily be prevented by the use of proper supports to the masonry.

The arrangement has this advantage over the usual one, that it admits of the delivery of the fumes and dust from the cylinder directly into the main dust chamber, which, in this case, was a flue running transversely to the axis of the cylinder, 6 feet high, 3 feet wide, and 17 feet long, while a small opening in the wall, opposite to the cylinder, closed with a loose brick when not required, enabled the workmen to inspect the interior of the furnace when in operation, or, by means of a long iron spoon, to take samples of the ore for examination.

At a proper distance from the opening in the flue wall which received the neck of the cylinder, a second similar opening was left for the introduction of a second cylinder when required, being, in the meantime, of course, temporarily closed with masonry, just as "blind windows" are made in houses.

Conveniently situated openings at the base of the wall, closed by means of sheet-iron doors when not in use, enabled the removal of dust from the chambers without the necessity of stopping and cooling, so that a man could enter, though one of these doors was large enough to admit a man, the others being intended merely for the passage of a hoe.

The extent of dust-saving space was, first, as already said, a chamber at a right angle with the cylinder, 17x6x3 feet, and secondly, another chamber forming a right angle with the first, 10x6x2 feet, after which the bottom gradually rose, till, in the length of 10 feet, the height was reduced to three feet, at which point was a vertical offset in which was a damper, followed by another flue, 20x3x2 feet, connecting with the stack. I mention these dimensions because, though the space would appear to be ample for a single furnace, yet it was found that a considerable quantity of dust escaped, nor was the loss materially diminished by the subsequent insertion in the first two chambers of a number of vertical sheet-iron deadairs, which, however, did some good.

The cylinder was lined with common bricks of very inferior quality, placed with the narrow sides to the shell, without breaking joints, each brick being slightly beveled by grinding it against another, and dipped in a thin paste of clay and water. The ends were lined with fire tiles, which seems to be a needless expense. The iron firebox was also lined with common bricks.

The lining of the cylinder was placed without breaking joints, in opposition to the advice of the mason, because the bricks were of such unequal thickness that to have done otherwise would have necessitated the use of a great deal of clay between some of them, and while I doubt the expediency of breaking joints in any case, I am satisfied that, under the circumstances, it was decidedly better not to do so.

In practice I found that at first, while working a very "dry" (infusible) ore, a few bricks dropped out from time to time. The vacancies thus formed were filled with a mixture of clay, sand and ashes, slightly moistened and beaten in, which answered perfectly, and I am inclined to think it might be better to line the whole cylinder in this way in the first place, as there are so many boltheads and other projections in the way, not to speak of the diaphragm, that the cutting of bricks to fit them is tedious, expensive and wasteful. However, after some ore containing a good deal of lead had been roasted at a pretty high heat, the interior of the cylinder became so crusted and impacted with ore that there seemed to be no further danger of the falling out of the lining.

The common bricks in the firebox proved unfit to withstand the heat at that part for any great length of time, and would be advantageously replaced by firebrick. The conical throat of the cylinder, through which the flames enter, being exposed to great heat, was necessarily lined with firebrick, and to keep them from sliding out, I found it necessary to rivet a rib or flange into the iron shell, a notch being cut in the bricks to fit it.

I regret that I cannot give any statistics as to the quantity of fuel consumed in this furnace, as the wood was not measured, but as circum-

stances prevented continuous working, roasting being carried on only during 12 hours, or less, in each 24, it is certain that a great deal more was burned than would have been necessary under other conditions in proportion to the work done; yet I can say with confidence that the economy of this furnace, as compared with the reverberatory, is immense.

The working capacity of the cylinder is about 50 cubic feet of pulp to the charge, and the time required is from 3 to 8 hours, including charge and discharge; and as the weight of this volume of pulp varies with the quality and fineness, and the time required varies with the same circumstances, but in the opposite direction as regards amount of work done, I conclude that a single cylinder is competent to roast, on an average, from 8 to 12 tons in 24 hours, and one man on a shift can do all the work.

In working it was observed that a dense cloud of dust escaped from the stack during the first part of the roasting, or until the ore began to assume the "spongy" consistency characteristic of the chloridizing stage, when the dusting gradually ceased. The dust recovered from the chambers and flues amounted to from 10 to 15 per cent. of the ore treated; in richness it was equal to the ore, and about 60 per cent. of the contained silver was soluble in solution of sodium hyposulphite.

It is usual to work the dust without re-roasting, on account of the supposed difficulty of preventing it from passing immediately out of the cylinder with the draft, but I succeeded perfectly by moistening it with a solution of salt and iron sulphate before returning it to the roasting. The first ore worked was of such a character as not really to require roasting, and was specially ill-adapted to treatment in a furnace of this class, where the ore must fall literally through a gale of wind. It contained but little sulphur, while the silver was chiefly in the form of a soft, friable substance in the cavities of the quartz gangue. It contained \$197 silver per ton, and of this only 77 per cent. was saved, while the tailings carefully and thoroughly sampled only retained \$13 per ton, proving conclusively that a heavy loss had been sustained in the roasting. After this the results were more satisfactory, the ore being of a better quality for roasting, containing more sulphur, and the silver being in better form. The value ranged from \$40 to \$250, averaging \$74 per ton in silver, and the yield was 82 per cent. The assays of tailings still showed a considerable though much reduced loss in roasting, probably about 8 per cent.

It should be observed, in judging the work of this furnace, that the conditions were rather unfavorable. A portion of even the latter worked ore was deficient in sulphur; the furnace was worked irregularly, part of the time by a green hand. The ore also was crushed too fine. The assays for soluble silver in the roasted ore, made with sodium hyposulphite, or hot brine, seldom gave less than 90%, and sometimes gave more, and the assays of tailings, never extravagantly high, were sometimes as low as three or four dollars to the ton.

Ore to be roasted in any furnace of the class of revolving cylinders with "grooves, cavities or projections," by which it is lifted and showered through the flames, should be crushed only just so fine as is found absolutely essential for the complete roasting of the particular ore in hand. In some cases, as that of the La Dura ore, in Mexico, a screen of 18 or 20 meshes to the linear inch is sufficient, but when the metalliferous particles are inclosed in a compact gangue it may be necessary to crush finer.

It is also advantageous to have the particles as nearly as possible of equal size, which is promoted by thorough drying before crushing, and by abundant screen surface in the battery, with high speed of stamps; still more by having a very coarse screen in the mortar, and an arrangement for resifting, and returning to the stamps the coarser portion of the pulp.

It is frequently claimed for the different mechanical furnaces that they dispense with the necessity for skilled labor. I do not assent to this, for it is as necessary for the workman who has to work and care for a Bruckner or White roaster to possess skill and to pay attention, as it would be in working a reverberatory, or rather more so, the advantage being in the saving of labor and fuel which they effect, the latter especially in the White furnace, when receiving ore at the cooler end, as the waste heat as well as vapors of salt, sulphur, etc., which are evolved under the finishing heat at the other end of the cylinder, are utilized in roasting and partly roasting the continuously incoming ore, which cannot be the case in a furnace which works by charges.

There is, however, one drawback to the White furnace from which that of Bruckner is free, which is, that if the workman, through ignorance or neglect, or owing to a change in the character of the ore, fails to keep up the degree of heat needed for chloridizing the ore, which at a certain stage in the roasting is almost as mobile as a liquid, runs through the cylinder "like water," and must be returned and passed through again.

However, I do not wish to make comparisons between the two furnaces, for I consider both to be splendid examples of invention, and as I think there are cases and places where either may be superior to the other, I hope the inventor of each may reap the just reward of his ingenuity and perseverance.

C. H. A.

THE House bill, appropriating \$500,000 for the Eads jetty system, was reported back adversely by the Committee on Appropriations.

Items of Interest from the Mines.

We give below items of interest from prominent mines, most of which are collated from letters of the respective superintendents on file at the offices in this city. Considerable of this news is later than that procured from the interior journals:

The amount of bullion produced by the Empire (Grass Valley) in a run of 20 days was \$17,782.

In the Comanche all the ore stopes and breasts above the 550-levels are looking as well as usual and keep the mill supplied with ore.

The works of the Lady Bryan when finished will be complete in every respect and capable of working to a depth of 2,000 feet, and will compare favorably with any on the Comstock.

In the Justice the ore producing sections throughout the mine continue to look well, yielding their uniform grade ore. In the 800-foot level, as a whole, at no time since the level was opened was the general aspect brighter, in all prospecting points, than at present.

A letter from the Superintendent of the Manhattan, dated the 2d, says: During the past month the mill has reduced 517½ tons of ore. We also shipped \$100,310.45 worth of bullion. The clean-up has not yet been obtained, the pans being now stopped for that purpose. At the Frost shaft the 500-foot east stope shows much improvement, the ledge having increased in size and is continuing in high grade ore. In the 500-foot west stope a large quantity of fine ore is being extracted. To-day's samples assay \$251.33. The 517-foot continues to produce the same quantity of ore, but it is of a higher grade, to-day's samples assaying \$265.45 per ton.

From every indication the great amount of dead work now being performed in the Golden Chariot will open up large bodies of ore for milling in addition to the reserves now developed in 4th, 5th and 6th levels. All work of hand is progressing with the greatest dispatch and economy.

The chloriders in the Meadow Valley are still operating in the old abandoned levels of the mine, but revenue from that source has been rather light, as the ore extracted is of low grade. Owing to the extreme cold weather the parties engaged in concentrating the tailings at Dry Valley mill have been compelled to discontinue operations until the weather moderates.

In the Hale & Norcross they find that the north drift on the 1900-foot level, connecting with the Savage mine, caved badly during the overflow and rise of water reported last week.

They could not get in more than 57 feet on the 1700-foot level of the Gould & Curry mine, with the diamond drill, and they found nothing but porphyry. They are now drifting again to pass the ground that stopped them, and will then again commence drilling. The Superintendent says: It is unfortunate that we could not continue drilling on the 1700-level, as it is much the cheaper plan of prospecting deep, hot mines. I think in two weeks we can get the drift far enough ahead to use the drill again, and then can determine, at the rate of 50 feet per day, the prospect of finding anything east on this level.

On the 1650-foot from the C. & C. shaft they have had a decided change the past few days in the character of the ground, also have encountered some water. The rock is hard blasting and the water increases the heat and our progress will be necessarily slow until connection is made with some of the winzes.

The last clean-up of the Eureka (Grass Valley) was 325 ounces of amalgam.

The Manhattan Mining Co.

The annual meeting of the Manhattan mining company was held on Wednesday. John A. Paxton (President), J. D. Fry (Vice-President), A. K. P. Harmon, W. S. Sage and James S. Porteous were elected Trustees for the ensuing year. John Crockett was chosen Secretary, and Allan A. Curtis Superintendent. There were 45,817 shares represented. From the President's report we extract as follows:

During the year ending December 31st, there has been reduced 6,232½ tons of ore, producing \$1,229,679.57, being an average of about \$198 per ton. The receipts from other sources were \$3,686, making a total of \$1,233,366. Among the items of disbursements are, for ores extracted and tributes paid, \$445,988.38; reduction, \$183,377, being \$29.43 per ton; discounts and freights, \$170,477; paid for ores purchased, \$171,047; for permanent improvements, \$35,821, which includes the erecting of three sets of hoisting works. The total profits of the year were \$217,517, including four dividends of \$50,000 each. The heavy discount upon bullion has greatly reduced the profits, last year's outlay being \$99,769 greater than it would be at present upon the same amount of bullion. The mining expenses have been unusually large, owing to there having been a large amount of ground opened up, and which is now accessible for stoping. The prospects for the coming year are quite as favorable as they have been at any time during the past. There is a surplus on hand of \$68,246.70.

PROFESSOR THOMAS PRICE, of this city, has been appointed a member of the Assay Commission, which meets in Philadelphia on February 14th.

PATENTS AND INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

FOR WEEK ENDING JANUARY 30TH, 1877.
VETERINARY SURGICAL INSTRUMENT.—Lewis Woods Hamilton, Pendleton, Ogn.
SELF-ACTING STRIPS FOR MINING BUCKETS.—Henry S. Craven, B. F.

COIN WRAPPERS.—Ethan A. Scott, S. F.
METHOD OF SAWING LUMBER.—Jason Springer, S. F.
CAR STARTERS.—Samuel S. Vollum, S. F.
BOOK CLAMPS.—George F. T. Wood, S. F.

EXPLOSIVE COMPOSITIONS.—Egbert Judson, S. F.
The patents were not ready for delivery by the Patent Office until some 14 days after the date of issue.

NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s Scientific Press American and Foreign Patent Agency, the following are worthy of mention:

COIN WRAPPER.—E. A. Scott, S. F. Where silver coin is used in large quantities it is customary to make it up into twenty-dollar rolls, these rolls being enveloped in a brown paper covering, and when these rolls bear the mark or advertisement of any responsible firm, they are accepted as correct without the delay of unrolling and examining them, being simply weighed. This practice has led to attempts to defraud, either by inserting smaller coins between the half dollars in such rolls or by taking a piece of lead pipe, filing it until the proper weight is reached, and placing a real coin at each end of the roll, so that unless entirely opened the fraud will not be detected. Mr. Scott's invention is a wrapper for these packages of coin, to hold them in convenient shape for business transactions, and at the same time expose the coin so that at a glance the nature of the package can be determined without the trouble of unrolling and examining. These improved wrappers are formed of the usual size and material, and with a properly constructed die they are perforated with round holes. These holes are made in sets so as to extend from end to end of the roll, and are placed at such a distance apart that when the necessary number of thicknesses of paper have been rolled about the coins, the holes in the outer layer will exactly fit over the holes in the inner layer of the envelope. In order to expose all the coins there are two sets of holes, and one set stand opposite to the covered space between the other set, or, in other words, break joints with them. A sufficient space is left for advertisements upon the outside of the wrapper, and from the shape of the holes the strength of the material will be preserved, while the necessity for unrolling the coins will be avoided.

CAR BRAKE AND STARTER.—S. S. Vollum, S. F. This invention relates to an improved arrangement for operating brakes on street cars, and also to the combination with said brake operating mechanism of a device for enabling the driver, or other person standing on the platform of the car, to assist the horses in starting the car from a state of rest. This car starting device will be specially useful in case the horses, or either of them, should balk or refuse to pull, as the driver can start the car himself and thus relieve the horses of the strain until it gets started, which will generally set the balky horse to work. In case of accident to the brakes on a side hill or incline, as often happens, the chain used in the device will enable the driver to hold the car until the wheels are blocked. This brake and starter can be operated from either end of the car.

SELF ACTING TRIP FOR MINING BUCKETS.—H. S. Craven, S. F. This is a novel device for dumping and discharging buckets from mines or wells, when they arrive at any level where it is desired to empty them. It consists of an attachment for the bottom of the bucket, which will engage with a slot in the discharge chute, and when the bucket is lowered over the chute will reverse and empty it.

The worst apprehensions are felt of a strike of the Durham colliers in consequence of a difference with the masters about the recent arbitration awards. The strike would directly effect from 30,000 to 40,000 men, and would involve the stoppage of the Cleveland iron industry.

The report of the North Bloomfield mining company, which we received this week, is one of the most elaborately arranged, and contains more definite information, than any mining company's report we have seen for a long time. We shall give an abstract of the report in our next issue.

WOODWARD'S GARDENS embraces an Aquarium, Museum, Art Gallery, Conservatories, Tropical Houses, Menagerie, Seal Ponds and Skating Rink.

The Bressa Prize for Scientific Work.

At the last meeting of the California Academy of Sciences a communication was received from the Academy of Sciences of Turin, Italy, giving the details concerning the "Bressa prize," a matter of some interest to scientists in all parts of the world. The communication contained the following information:

The last will and testament of Cesare Alessandro Bressa, doctor in medicine and surgery, signed the 4th of September, 1835, contains the following clause: "I leave all my property, present and future, after paying certain legacies, to the Royal Academy of Sciences, Turin. The Academy may be represented by its Secretary, or by any attorney elected for that purpose by its resident members. On the decease of Signora Claudia Amata Dupeche, who has a life interest in all my possessions, the Royal Academy of Sciences of Turin will immediately enter in possession of everything and may sell ground property, put capital out to interest in any and whatever way it may find most profitable, and with the interest of this property a biennial prize is to be established, which will be adjudged in the following manner, viz.: The net interest of the first two years to be given in premium to that person, of whatever nation or country he be, who shall have, during the previous four years, made the most important discovery or published the most valuable work on natural and experimental philosophy, natural history, mathematics, chemistry, physiology and pathology, as well as geology, history, geography and statistics. The net interest of the following two years to be given only to an Italian, who, by judgment of the above named Academy of Turin, shall have made the most important discovery, or have published the most important work, on any of the above mentioned sciences. The prizes will continue to be distributed in the same order."

While fully aware of the great responsibility which rests on it in being called to judge the productions of human intellect in a sphere so vast as to comprise nearly all the positive sciences, the Academy has accepted the task with the intention of fulfilling to the utmost the generous wishes of the testator with regard to the promotion and advancement of science. The Bressa legacy remained free from all claims in the month of July, 1876, consequently the first biennial term mentioned in the will, will include the years 1877-78. The first prize will be given in the year 1879 to the person, of whatever nation or country he be, who shall have, during the four previous years, made the most important and useful discovery, or published the most celebrated work on any of the above mentioned sciences. The value of the first prize amounts to 12,000 lire.

In accordance with the spirit of Dr. Bressa's will, the Academy will choose the best work of discovery, whether or not it be presented by the author. The prize, in no case, will be given to any of the national members of the Academy of Turin, resident or non-resident. In the year 1881, the second Bressa prize will be given for the preceding quadrennial term of 1877-80, according to the above rules, except that in obedience to the testator's wishes it can only be conferred on an Italian. And so on, every four years there will be a Bressa prize for competition among scientific men of any part of the world, and every four years a Bressa prize which can be competed for by Italians only.

Mining and Other Companies.

Aetna Tunnel Company.—Location of
principal place of business, San Francisco, California. Location of works, Alta City, Salt Lake County, Territory of Utah.

Notice is hereby given that at a meeting of the Board of Directors, held on the 22nd day of January, A. D. 1877, an assessment (No. 1) of three cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary, at the office of the company, Room 6, No. 420 California Street, San Francisco, Cal.

Any stock upon which the assessment shall remain unpaid on Monday, the 26th day of February, 1877, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 19th day of March, 1877, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

JAMES M. HAYEN, Secretary.
Office, Room 6, No. 420 California Street, San Francisco, California.

Dolores Consolidated Mining Company.
Location of principal place of business, San Francisco, Cal. Location of works, Dolores Mining District, Esmeralda County, Nevada.

Notice is hereby given that at a meeting of the Board of Directors, held on the 22nd day of January, A. D. 1877, an assessment (No. 1) of ten cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, 418 California Street, San Francisco, Cal.

Any stock upon which the assessment shall remain unpaid on the 14th day of March, A. D. 1877, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Wednesday, the 11th day of April, 1877, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

J. W. CLARK, Secretary.
Office, Room No. 2, 418 California Street, San Francisco, California.

Great Blue Gravel Range Company.
Location of principal place of business, San Francisco, State of California. Location of works, Placer county, State of California.

NOTICE.—There are delinquent upon the following described stock, on account of assessment (No. 7), levied on the 22d day of December, 1876, the several amounts set opposite the names of the respective shareholders, as follows:

BERRY & PLACE

Selling Agents for the Pacific States,
Cor. Market & Fremont Sts., S. F.

THE O'HARRA CHLORIDIZING FURNACE

Guaranteed to Chloridize from 85 to 95 per cent. of any gold or silver ores that are not more profitable for smelting. Will also desulphurize ores and put them in proper shape for working in cupola furnaces.

Cost of Roasting and Chloridizing by this Process:

Two cords of wood at \$6.....\$12.00
Two firemen at \$4.....8.00
1,500 lbs of salt at 1¢.....22.50
Wear of shoes and power.....1.50

Cost for 15 tons.....\$44.00
Cost for one ton.....2.93¢

In a furnace of three or four times this capacity the cost is decreased by 20 per cent.

The furnace is now working successfully at the Poc Consolidated Co.'s mines in the Peavine District. For further information, apply to

D. J. O'HARRA,
Reno, Nevada.

The Ingersoll Rock Drill

Is Extensively Used in the East and

TAKES THE PLACE OF ALL OTHERS,
Wherever introduced, because it can be run with less power, labor and repairs, and do more work than any other Drill in the market. It has but few parts, is easily handled, being light, and has AUTOMATIC FEED, which saves labor. WE ASK FOR TRIAL AGAINST ANY COMPETITOR. For particular information regarding Drills or Air Compressors, send for circular to

H. W. JOHNS' ASBESTOS ROOFING AND PAINTS—Fire and Weather Proof.

ASBESTOS STEAM PACKING, made from pure long fiber Asbestos. Indestructible and Self-Lubricating. Circulars and Descriptive Pamphlets Sent Free.

PATENTED CAST STEEL SHOES AND DIES.

Guaranteed Cheaper than the Best Iron.

IMPORTANT NOTICE.

Reduction in Price from 16 Cents to 12 Cents Per Pound.

Owing to our largely increased business, the present low price of iron from which our Steel is manufactured, and the improved facilities for casting and forging, we take great pleasure in announcing that from and after this date we will supply our IMPROVED CAST AND FORGED STEEL SHOES AND DIES FOR QUARTZ MILLS at twelve cents per pound, delivered at San Francisco or Sacramento, instead of sixteen cents, as heretofore.

We also furnish Steel Plates for Blake and other Ore Crushers, Steel Gut Gearing, etc., for Mills and Hoisting Works, Steel Pan Shoes, Battery Cams and Tappets, etc., etc.

Address all orders, with dimensions or drawings, to

CAST STEEL SHOE & DIE CO.,

59 Nevada Block, S. F.

THE ASBESTOS PATENT FIBER COMPANY,

Two Medals of Honor. Of Philadelphia, offer for sale through their agent in San Francisco, Asbestos Steam Packing, Asbestos Boards and Asbestos Steam Joints.

Two Certificates of the Highest Merit.

All manufactured from the pure utilized Asbestos Patent Fiber, and under patents granted to J. S. Rosenthal. The packing is in all sizes from one-quarter to three inches in diameter, round, and free from all grit or mineral matter. The non-utilized or crude Asbestos, manufactured by some parties into packing, is impure and gritty, liable to injure the piston rod and should not be used. The packing made under the Rosenthal patents is of pure utilized Asbestos fiber, and a very superior article and entirely different from the so-called Asbestos packing heretofore offered for sale. It is compact in form, will not fuzz or disintegrate, and will wear much longer than any other kind of packing. The indestructible, expanding, contracting and lubricating qualities of Asbestos are now universally recognized, and packing made from it is peculiarly adapted for steam engines and pumps.

ASBESTOS PATENT FIBER BOARD.

This is the champion non-conductor, to prevent radiation of heat and condensation of steam, as covering for marine, stationary, or locomotive boilers and pipes, and for lining wood-work, where exposed to great heat. It is light, flexible, is not disturbed by vibration, and will not char or crumble. The sheets are 30 by 44 inches, of any desired thickness, and are easily applied.

ASBESTOS PATENT FIBER STEAM JOINTS.

Indestructible by fire or water, expands and contracts in a desirable manner, adjusts itself to any rough point, is cheaper than rubber, and in all respects a superior article. PURE ASBESTOS FIBER for packing steam governors and other purposes. All these goods are extensively used in the Atlantic States and give general satisfaction.

PHILIP HINKLE,

DEWEY & CO. American & Foreign Patent Agents

OFFICE, 224 SANSOME STREET, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent Reissues taken out Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Baden, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Granada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule price for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) SOONER than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more correctly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

Home Counsel.

Our long experience in obtaining patents for inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing to them the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

HOTEL OF THE NETHERLANDS, PORT SAID, EGYPT, OPENED on the 1st of DECEMBER, 1876.

THIS ELEGANT HOTEL IS SITUATED ON THE MEDITERRANEAN AND AT THE ENTRANCE OF THE SUEZ CANAL, AND COMBINES WITH THE COMFORTS OF THE FIRST-CLASS HOTELS OF EUROPE THOSE OF THE ORIENT. IT IS RECOMMENDED TO THE TRAVELING PUBLIC ON ACCOUNT OF ITS VERY BEAUTIFUL AND HEALTHY SITUATION, AND MORE ESPECIALLY TO PERSONS OF DELICATE HEALTH, WHO ARE OBLIGED TO SEEK A SOUTHERLY AND MILD CLIMATE DURING THE WINTER MONTHS.

The Hotel contains Dining, Smoking and Billiard Rooms, Ladies' Drawing and Reading Rooms, the latter supplied with all the most important Papers, and possesses a Pretty Garden with Fountain, which is protected against the rays of the Sun during Daytime and illuminated in the Evening, and offers to the Visitors of the Hotel an agreeable resort. All Public and Private Rooms command a view on the Sea, the Canal, and the Garden. Hot and Cold Baths in the Hotel.

F. MEYER, Manager.

PICKERING ENGINE GOVERNOR.

VALLEJO FOUNDRY, October 17th, 1876.

Messrs. NEYLAN & YOUNG, San Francisco,

Agents for "PICKERING GOVERNORS."

Gents:—The 10 two-inch Improved Speed Adjusting Governors I bought of you this year for my patent Straw Burning Threshing Engines give splendid satisfaction. They far surpass for regularity of speed any Governor that I have ever seen, and I have seen all the best kinds; I have seen the main belt fly off the pulley several times this season while threshing, and the engineer did not discover it, so perfectly was the speed maintained, until he was told of it; this I consider something wonderful; I consider the Governor absolutely perfect, so far as speed is concerned. I bought and put on to one of my engines a Shive Governor, to see which was the best, and after one season's trial I have no hesitation in saying they are superior to any other Governor that I have seen or used. I wish you would send me the lowest price that you can furnish 25 Governors for next season's engines. Yours respectfully,

J. L. HEALD.

The only Governor that has received awards at each of the International Exhibitions. American Institute Fair, New York, 1865, Two Medals; Mechanics' Institute Fair, Baltimore, 1865, Silver Medal; American Institute Fair, New York, 1869, Two Medals; International Exposition, Paris, 1867, One Bronze and Two Special Medals; International Exposition, Vienna, 1873, Medal of Progress and Decoration; International Exhibition, Philadelphia, 1876, Medal and Diploma.

UNITED STATES Mineral Land Laws, Revised Statutes, AND INSTRUCTIONS AND FORMS UNDER THE SAME.

We have just issued a pamphlet containing the General Mineral Land Laws of the United States, with instructions of the Commissioner of the Land Office. The contents of this pamphlet comprises all of the Government laws with relation to mineral lands of interest to the mining community, as follows: Mining Statute of May 10th, 1872, with Instructions by the Commissioner of the Land Office; Mining Statute of July 26th, 1866; Mining Statute of July 9th, 1870. Forms required under Mining Act of May 10th, 1872, as follows: Notice of Location; Request for Survey; Application for Patent; Proof of Posting Notice and Diagram of the Claim; Proof that Plat and Notice remained Posted on Claim during Time of Publication; Registers' Certificate of Posting Notice for Sixty Days; Agreement of Publisher; Proof of Publication; Affidavit of \$500 Improvements; Statement and Charge of Fees; Proof of Ownership and Possession in Case of Loss or absence of Mining Records; Affidavit of Citizenship; Certificate that no Suit is Pending; Power of Attorney; Protest and Adverse Claim; Non-Mineral Affidavit; Proof that no Known Veins Exist in a Placer Claim, etc. There is also given the U. S. Coal Land Law and Regulations thereunder. The work comprises thirty pages, and will be sold, post-free, for 50 cents. It should be in the hands of every one having any mining interests. DEWEY & CO., Publishers of the MINING AND SCIENTIFIC PRESS, S. F.

The Explorers', Miners' and Metallurgists' Companion.

Comprising a Practical Exposition of the Various Departments of Exploration, Mining, Engineering, Assaying, and Metallurgy,

Containing 672 Pages and 83 Engravings,
BY J. S. PHILLIPS, M. E.,

Of California, a Practical Operator for Thirty-four Years; Explorer, and Resident in the Pacific States and Territories for the past Eight Years.

PRICE—bound in cloth, \$10.50; in leather, \$12. Forwarded by mail for 50c. extra, at the MINING AND SCIENTIFIC PRESS Office, by DEWEY & CO.

KUSTEL'S CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver ores generally, with 120 Lithographic Diagrams, 1867. The most complete treatise. Published at this office. Price, \$5. Postage, 50 cts. extra.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS Office, S. F.

BY GUIDO KUSTEL,

MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their respective Metals without Quicksilver. 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore. It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. Price, \$2.50 coin, or \$3 currency, postage free.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Millman, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. PRICE REDUCED TO \$5.

Much Obligated, Etc.

PORTLAND, OREGON, June 26th, 1876.
Dewey & Co., Patent Solicitors, S. F.—Gents: I am much obliged to you for courtesy shown me, and am well pleased with the manner in which you have done my business, and assure you, will cheerfully recommend you to my acquaintances needing such services. Hope to have a case again before long, of my own. I have been an inventor all my life, but let others reap the benefit, or had work stolen from me. Please have the extra copies of my patents sent, etc., mailed to me direct, and oblige. Yours truly,
J. H. WOODRUM.

WOODLAND, CAL., Aug. 8th, 1876.
Messrs. DEWEY & CO.—Gents: Your letter containing the patent for my Centennial churn has come duly to hand, and you will please accept my many thanks for the prompt manner in which you attended to the business entrusted to your care, and I will take great pleasure in recommending you to any one having anything to attend to in your line. I am having a number of the churns put up, which will be ready for sale in a few weeks.
Yours truly,
JAMES ROOT.

Webster's Unabridged.

3,000 Engravings; 1,840 Pages Quarto. Price, \$12.

A NEW FEATURE.

FOUR PAGES COLORED PLATES.

The National Standard.

PROOF,—20 TO 1.

The sales of Webster's Dictionaries throughout the country in 1876 were 20 times as large as the sales of any other Dictionaries. We will send proof of this on application, and such sale still continues.

More than THIRTY THOUSAND copies of Webster's Unabridged have been placed in as many Public Schools in the United States, by State enactments or School Officers.

Webster's Dictionary has been recommended by State Superintendents of Public Instruction in Eastern, Northern, Middle, Southern and Western States,—TWENTY-EIGHT in all.

Can you better promote the cause of education and the good of community than by having a copy of Webster's Unabridged in your family, and trying to have a copy in each of your Schools?

Webster now is glorious,—it leaves nothing to be desired. [Pres't Raymond, Vassar College.]

Every scholar knows the value of the work. [W. H. Prescott, the Historian.]

Believe it to be the most perfect dictionary of the language. [Dr. J. G. Holland.]

Superior in most respects to any other known to me. [George P. Marsh.]

Testing and Working Silver Ores.

The above is the title of an illustrated work of 114 pages, for miners and prospectors, by Chas. H. Aaron, which has just been issued by Dewey & Co. Mr. Aaron has managed to give many useful hints and suggestions, free from all technicalities, and in such a style as to be easily comprehended. It is written for the miner, with no chemical symbols or metallurgical technicalities to confuse those who are not chemists or metallurgists. The following summary of the contents of the work will give an idea of its scope.

Under the heading of the first chapter, "Testing Ores for Silver," we find paragraphs on ore formation, test for silver, with heat and water, acid or blow pipe. In speaking of testing for a process, the extent and richness of ore is considered, smelting ores, selecting and working sample, appliances for testing, roasting, etc. Under the head of "Working Ores" the author describes Aaron's process, has something to say of superheated steam, preparation of dichloride of copper and protochloride of copper, use of copper and iron, quantity of chemicals, carbonate of lime, chloride ores, amalgam, Patchen's process, etc. He also describes the methods of working roasted ores, treatment of base metals, stirring, heat of furnace, want of sulphur, etc. Under the head of "Leaching Processes" are the titles, Smelting, Mexican process, Chilean process, Kroenke's process, etc. Under "Pulverizing Machines" are described the arastra and its construction and operation, stamp batteries, screens, Crocker's trip-hammer battery, Paul's pulverizing barrel, Kendall's battery, Noice's pulverizer, a cheap rock breaker, etc.

In speaking of amalgamators the author describes a cheap amalgamator, grinding the ore, directions for making a barrel, preventing mechanical wear, use of quicksilver, copper in bars, Freiberg barrel, cheap barrel, trough, barrel on rollers, Aaron's amalgamator, separator, etc.

He describes an improved retort, roasting furnace, furnace tools and furnace building. Among the miscellaneous mention may be found Aaron's leaching apparatus, with two or three different arrangements, a small mill, sampling tailings and settling tanks, dichloride of copper, etc. Mr. Aaron is a practical miner, of long working experience on this coast.

The book is a serviceable one for miners' and prospectors' use. Price, post free, (in leather,) \$2.00. Address Dewey & Co., MINING AND SCIENTIFIC PRESS, 224 Sansome Street, San Francisco.

Number 7.

A Home for the Sailor.

Some 10 or 12 years since a number of philanthropic ladies of this city formed an association to secure a home for sailors, where they might be properly taken care of while in port and protected from the impositions and robberies of unscrupulous men. These ladies have worked long and earnestly, by holding fairs, soliciting personal contributions, etc., until they had accumulated a fund of some \$16,000 or \$18,000, with which they purchased a suitable lot about a year ago on which to erect a home.

Soon after that purchase, at the suggestion of several prominent citizens, they prepared a memorial and petition to Congress for the use of the old marine hospital building, corner of Harrison and Spear streets, for the purpose of a home. Through the exertions of our delegation in Congress, the petition was heard and granted, and some three months since the ladies were put in perpetual possession of that property for the uses specified—the same to revert to the government whenever its uses were diverted. This is better than owning the property, as while the title rests in the government the property is not liable to taxes of any kind.

The building is now in process of thorough renovation, at an expense of some \$15,000, including furnishing—the money thus far having been raised by selling the lot belonging to the society, for which they now have no further use. The home will be opened about the first of April, and will form one of the largest, most convenient and most complete institutions of the kind in the world, and capable of accommodating from 400 to 500 persons. It will be, indeed, a "Palace hotel" for poor Jack, which he will no doubt fully appreciate. It will be provided with a library, reading room, lecture room, etc., and will be a place where seamen can find good board and lodging at fair rates, and where they may pass their time while in port out of the way of the pernicious influences to which they are now subjected. We give annexed a view of the building, which is worth over \$100,000 as it stands. It is located on a slight elevation commanding a fine view of the city and harbor, and forms a most conspicuous object to the mariner as he enters the port.

The work of the ladies has been, for years, a most untiring and arduous one, and one which, by the liberality of the general government, has been finally crowned with most abundant success. These ladies deserve the gratitude of the whole community for this national work in behalf of our seamen. We know that it is most fully appreciated by the leading merchants and ship owners of this city.

The lady officers and managers of the society are: Mrs. C. D. Knight, President; Mrs. Capt. Henry Tucker, Recording Secretary; Mrs. P. S. Williamson, Corresponding Secretary; and Mrs. E. D. Cogswell, Treasurer. Their associates in management are Mrs. A. E. F. Baker, Jane Rowland, B. F. Lambert, R. Barclay, G. Burrows, W. B. Ewer, A. W. Loomis, J. Hughes, A. Kohler and W. Rielly. The President and Secretaries are Trustees.

Their Advisory Board are Capt. Oliver Eldridge, L. M. Kellogg, Hon. E. D. Sawyer and W. B. Ewer, all men having the confidence of the public.

A table prepared by Harry C. Hoyt, marine reporter to the Merchants' Exchange, shows that fifty vessels were built on the Pacific coast last year, at a total cost of \$1,021,100, divided as follows: Steamers, \$220,000; sailing vessels, \$631,100; two revenue cutters, \$175,000.

A MINERS' union is being formed at Darwin, Inyo county.

THE BLACK HILLS.—Not all the reports which come from the Black hills are rose-colored by any means. Some of the miners there have a very poor opinion of the country. One of these is Robert Evans, an old resident of Nevada, and now in the Black hills country. In a letter to the *Eureka Sentinel* he says: I think I know a little about placer mines, and I am convinced that this is about as poor a mining country as I ever struck. There are a few claims that have paid well, but they are very scarce. In Montana, in early days, you could see some fat

Scenery on the Columbia River.

The Pacific coast is rich in natural scenery from end to end. It has the grand elements of mountains and rivers to weave into its landscapes. The glaciers and rivers in many cases have been the sculptors and the mountain sides have been the marble. The result is a most wonderful variety of rock exposures, which command the silent admiration of the one who views them because of their grandeur and magnitude.

SAN FRANCISCO SAILORS' HOME.

sacks of gold-dust, but they are as scarce here as hens' teeth. I see by the Eastern papers that thousands are coming here in the spring from the States. They will be disappointed like myself and plenty of others, and wish themselves out of here again. I do not know what they will do for a living, unless they join Sitting Bull or General Crook's army. My advice to all old acquaintances is to stay where they are. Do not believe the big stories you read in the pa-

These remarks are especially true of the scenery of the Columbia river of the north. The little sketches which we present on this page this week represent scenes which are sublime in their proportions.

Only a short distance above Cape Horn, on the south, or Oregon side of the river, is situated a perpendicular rock of peculiar basaltic formation, "Rooster rock," and still another, which rises from the middle of the river for

tains of California, and are the central range. The eastern ridge is above the great falls of the Columbia. The western is along the shore of the Pacific ocean, called the Coast range.

The Columbia has three large falls in the distance of 700 miles: the Cascades, 130 miles from the ocean; the falls of the Columbia, 40 miles above the Cascades; and the Kettle falls, 530 miles above the Columbia. Besides these falls, there are many dangerous rapids. On the Southern Columbia, Lewis, or Snake river, as it is more commonly called, which unites with the main river a few miles above Old Fort Walla Walla—now Wallula—there are two great falls, known as the American and Shoshone, the latter being 362 feet perpendicular, with cliffs towering on each side 1,000 feet from the water's edge.

The Cascade range is the most important of the three ranges of mountains named, and derives its name originally from the great number of beautiful cascades which pour out of almost every ravine and crevice of the mountains, many times from the very summit, presenting in the sun's rays a grand constellation of glittering jewels.

For varied and remarkable scenery the Columbia, for 1,000 miles from its mouth, is certainly the most notable of any river in the world. The most magnificent views of earthly scenery are presented from different points. High mountain peaks, covered with perpetual snow, are to be seen in all directions. Among these peaks the most notable are Mt. Hood, Mt. Jefferson, Mt. Adams, Mt. St. Helen, Mt. Rainier, and the Three Sisters. The sight is grand beyond description. At places the country, as viewed from the river, looks barren and worthless, and the waters move sluggishly towards the sea. At others, the country presents the most beautiful appearance, with gardens, vineyards, crops and herds—a perfect Elysium. Again it is covered with thick forests of heavy timber—or the broad, rich bottom lands are awaiting the husbandman to yield a thousandfold the seed sown.

CORK OAK.—The Santa Barbara Press says: Commissioner Watts, of the National Agricultural Department, has asked for the results of a

distribution of cork acorns made by his office. In response we state that 15 years ago Mr. Hinchman, of San Diego, then resident here, received some acorns from Washington, and planted some and gave five (described as being 2½ inches long) to Captain Trussel. Those planted by Mr. Hinchman failed to live, and of the five planted by Captain Trussel four were destroyed by squirrels. One tree is now standing on the lot at the corner of Montecito and Castillo streets. It is an evergreen oak about 20 feet high and covers about as much area. At the foot it is 40 inches in circumference, and six feet from the ground, where it begins to branch, it is 30 inches in circumference. The leaf is very similar to the California live-oak, except that the under side is whitish. The tree, though carefully watched, has never been known to fruit. As Captain Trussel does not permit specimens to be cut we had to be satisfied with sticking a knife into the bark; it penetrated readily through a smooth, good quality of cork bark to a depth of an inch and a half. As all cork used in the United States is imported, and the wine interest of California is growing so fast, it may be well worth while for our enterprising agriculturists to plant the cork acorn, as this soil and climate are eminently well adapted for it.

THERE is a rumor from the English coal regions which is calculated to alarm English miners. It is to the effect that the proprietors of the mines have resolved to import cheap labor from China, and have already consulted the Chinese Ambassador on the subject. That official replied that he would undertake the management of the immigration, provided the immigrants were protected from insult and injury.

ROOSTER ROCK, COLUMBIA RIVER.
43 miles from Portland.

CASTLE ROCK, COLUMBIA RIVER.
57 miles from Portland.

pers, for there is nothing here to induce anybody to come. I shall leave as soon as possible and go back to old Nevada again, for it is a better country than this ever will be.

MORTGAGE ON THE SUTRO TUNNEL.—We see by the Nevada papers that a mortgage was placed on the Storey county records last week, executed by the Suto Tunnel Company to Robert and Hugh McCalmont and William Johnstone Newall, of London, England, covering all the property, franchises and improvements of the company, to secure a loan from the mortgagees to the company of \$124,321 already made, and further advances to be made in future.

some hundreds of feet, called "Lone rock," or "Castle rock." At another point a tiny stream of sparkling water pours over the cliff in one unbroken fall, 700 feet in height.

The Columbia river is navigable a distance of 130 miles, from the ocean to the Cascades, the head of tide water. At the Cascades, Dalles and several other places, railroads have been built around the falls and dangerous rapids, which connect with steamboats of light draft, which run up the Columbia and its numerous tributaries for 700 or 800 miles distant.

There are three general ranges of mountains west of the Rocky mountains, running in a northern and southern direction: the Cascades are a continuation of the Sierra Nevada moun-

CORRESPONDENCE.

Personal Suffrage in Mining Companies.

(Written for the MINING AND SCIENTIFIC PRESS.)

EDITORS PRESS:—Manhood suffrage is in this country the foundation of the political system (it being considered that the interests of non-suffragers are properly represented by their male protectors, individual cares of self-supporting females being looked upon as exceptional if not abnormal, and the injustice arising therefrom as illustration of the unavoidable imperfection of human institutions). The greatest good of the greatest number is regarded as the legitimate object of legislators, checked, however, by a due regard for the "inalienable rights" of the minority, or rather, perhaps, by a recognition of the fitness of things whereby the application of the principle is limited to cognate subjects of interest. Thus the property and feelings of the individual may be sacrificed to the material interests of the community, but life can only be taken in defence of life.

In accordance with these principles every male citizen (and vicariously, in theory at least, every female and minor) has a vote or a voice in the management of affairs; and if injustice is sometimes done to the minority the evil is reduced to a minimum by the check above referred to, and is submitted to as the inevitable result of human imperfection, being, in fact, regarded as a relative good, in view of the vastly greater evil which would result from a different course.

Why are these fundamental principles of republicanism ignored in the organization of our mining companies, where we seem rather to have borrowed a leaf of the history of the middle ages, where the power to do was confined to the favored few, and the many were permitted only to be and to suffer?

In politics there are many excellent reasons for thinking that the right or privilege of the suffrage should be permitted only to those who, by the accumulation of a certain amount of property, have proved their capacity, as well as desire to promote the public prosperity, and have, so to speak, given security for the proper use of the power which they desire to exercise, and so cogent are these reasons that in some very liberal governments this system is adapted in preference to ours (though to be perfectly consistent they ought to allow a man an increased number of votes in proportion to the increase of his "stake in the country," while we think it better to vest the right in, or grant the privilege to the man rather than his jackass or other possessions. But the arguments which are so potent in politics lose their force when applied to the government of a mining company, in which the greatest good of the greatest number will be best if not solely attainable by the principle of manhood, or more properly personal suffrage in its government, while the opposite principle makes the rights of the majority entirely dependent on the justice or magnanimity of the minority, and how slender a dependence this is, let the history of mining on the Pacific coast bear witness.

It may appear that the two cases are not parallel, since the possession of at least one share, which might be called a property qualification, is an essential condition of membership in a company, but the discrepancy is not material for our present purpose, and, indeed, disappears when it is considered that every member of society possesses at least his indivisible share in the national domain and all public property. The real difference lies in the fact that in the community the individual is enabled to segregate, to a certain extent, a greater or less quantity of property, which is, therefore, to a corresponding extent (not at all absolutely) under his own control, which is impossible in a mining company, but I think this difference is rather in favor of than against the view that the greatest good of the greatest number is best secured in the latter by the principle of personal suffrage.

I know it will be said that the interests of the wealthy investor must not be prejudiced nor his progress hampered by the necessities of his poorer partner, who, if he cannot "keep up his lick," must be content to lose his property in order that the great one may not be crossed in his wishes, or perhaps that the scripture may be fulfilled which says, "to him that hath much more shall be given, but from him that hath not (much) even that little that he hath shall be taken away," but I confess to a want of sympathy with the rich man in this case, who can certainly afford, at least as well as his weaker associate, to wait for his dividends, and to something more than a want of sympathy when, as is continually occurring here, he purposely increases the expenses or diminishes the product of a mine, being enabled so to do by the pernicious principle on which companies are organized, with the express object of "freezing out" his partners in the enterprise. The only legitimate agreement in favor of the present system is, that the interests of the community, to whom in the ultimate analysis it must be admitted the

mines belong, is furthered by their development, and consequently it is better that the privilege of working them should be granted in preference to those who are best able to prosecute that development; but, aside from the fact that there are other ways of attaining that object, as, for example, making the possession of a certain amount of capital a condition precedent to the occupation of a mine, as is done in some countries, I cannot, in view of the many wholesale frauds and robberies committed, of the widespread ruin, despair and devastation produced, and of the universal corruption of morals consequent upon the perversion of the spirit of enterprise to a reckless passion of gambling, all of which are the consequence of violent and unreasonable fluctuations in values, which again are largely traceable to rascally manipulations by or with the consent of "insiders," or are rendered possible by the constant uncertainty in the minds of the public as to the intentions of the said "insiders;" I cannot, I say, in view of these things, concede that the best interests of society are subserved by a system which thus sacrifices the best attributes of humanity to the supposed advancement of a purely material interest.

Under the system of personal suffrage in mining companies it would undoubtedly happen that individuals would occasionally suffer, but that is unavoidable and would happen much less often than under the present system, by which the advantage of the few is too often secured at the expense of the many, while it would undoubtedly result that the management of the mines would be purified, legitimate mining for profit would be encouraged, and stock gambling, by which I mean speculation in stocks without regard to the intrinsic merits of the mines, would no longer present such alluring inducements as now. The practice of "watering" stocks, ostensibly for the purpose of affording an opportunity to persons of moderate means to purchase, is in reality a part of the machinery by which the scattered dribbles of coin in the pockets of the million may be pumped up into the already plethoric coffers of the few, and is seldom resorted to by honest companies devoted to legitimate mining rather than to stock gambling; it should be discouraged, as should also the prevalent practice of forming companies with enormous fictitious capital, which can serve no other purpose than that of making the possible amount of assessments practically infinite. When a company is formed a reasonable and liberal estimate should be made of the amount of money required to accomplish its object, and to this sum the organic capital of the company should be limited, with a provision for its enlargement if found necessary, not by a clique of large owners, but by the votes of a considerable majority of the parties interested. In addition to the principle of personal suffrage, and to prevent evasion of its intent, it might be advisable to prohibit the practice of voting by proxy, and members at a distance might be permitted to send in their ballots by mail; nominations and candidacies would then be announced beforehand, and elections of directors would cease to be such a farce as they are. Also, it would not be difficult to devise some means by which minorities would be represented, to the great advantage of the company at large, since even minorities have rights, and occasionally good ideas.

I am aware that a majority of the present leading operators in mines would hold aloof from a company organized on the plan I propose, or on any plan which would prevent them from playing a "hogging game," and it is very possible that, for a time, mining stocks would be less eagerly sought after by the silly multitude who now throng "the slaughter house" on California street, sowing the seeds of the wind that they may hereafter reap the whirlwind. Be it so! With economy and honesty in the management of mines, and a genuine desire on the part of companies to make money by mining rather than by gambling, our mines would soon make a record which would offer inducement enough for legitimate investment, not only of our own, but of foreign capital also, while the inevitable fluctuations in values consequent on the vicissitudes of mining would afford abundant margin for legitimate speculation. As matters stand now with many of the "listed" stocks, the insiders are simply stealing and the outsiders are gambling.

I have no sympathy with the howlers in some of the daily papers who, because they have gambled and lost, choose to vituperate the management of the Bonanza mines, and clamor for restitution when it is clear that had they won they would have been the last to mention it, while some others must have lost to an equal amount. I think with you that it would better become such persons to grin and bear it, or, in more elegant phrase, to "suffer and be strong." Most of them knew that they were buying the mines at a most extravagant valuation, or else they never took the trouble to investigate that point; in either case were utterly indifferent to it, and simply hoped to be able to shift the burden and the loss on to other shoulders at some advantage to themselves. I would be ashamed to stand up before the public and cry "thieves!" as did one gentleman at a company meeting not long since, because, forsooth, having tried to cheat others I had cheated myself instead, or, which is the same, having speculated on a "point" I had found myself deceived. For what is a point? Simply a piece of surreptitious information touching the merits or finances of a mine, to the benefit of which all actual owners, or contemplating purchasers, have an equal right; or it is a glimpse of some intended rascality

on the part of insiders, and he who invests on the strength of it is virtually trying to steal; the only palliation of his conduct being found in the old saying that "there's no harm in stealing from a thief," for it is an undeniable, though a deplorable, fact that a very large proportion, perhaps all but you and I, dear reader, of those who are addicted to stock gambling, will not hesitate to avail themselves of a lie, either direct or constructive, or any other means practically within the pale of the law, by which they may obtain money, so that it is understood to be a game of diamond cut diamond all round, to the detriment of that private integrity which is the best bulwark of our liberties, and the decadence of which in the masses is the greatest danger to which those liberties are exposed.

But although individual sufferers are, perhaps, in most cases undeserving of sympathy, while those on whom so much obloquy is cast are doing no more than a majority of their victims would do had they the opportunity, it is none the less to be desired that a better state of things should be inaugurated, and as it is not safe to trust too much to human honesty under temptation, I hope to see some new system adopted in the organization of mining companies by which it will be rendered very difficult, if not impossible, for a few individuals to obtain absolute control over the property of many, and I think the first step in this direction is the adoption of personal suffrage in mining companies.

It is probably true that, as you say in a recent article on the subject, the managers of the Bonanza mines have done nothing contrary to the usual practice of persons in their position; yet, if it is also true, as generally believed, that the usual practice is not governed by strict integrity, that fact becomes their condemnation, and the statement is an admission that they are robbing their partners in the property day by day; and though I make no accusation against them, having no positive knowledge to justify my doing so, nor any direct interest in the matter, yet I may say that when parties, in control of the property of others, make a practice of letting contracts affecting that property to themselves, and profit enormously by so doing, the proceeding is at least open to suspicion, and, in common with most people who know anything of working ores, I am convinced that those of the mines on the Comstock can be worked to a much higher percentage than has been done (as a general rule) without greater expense to the company, if open competition was allowed and invited.

Not only do the mills engaged on these ores make a large profit on the price paid them for working, but the owners of the mills claim as their perquisite all the tailings, which, by the figures given in official reports, constitute, or will soon do so, a property of immense value in themselves. The highest average result of the milling that is claimed is 73 per cent. of the assay value of the ore. A large proportion of this value is gold, of which probably more than 73 per cent. is saved, so that the proportion of silver saved is less than 73 per cent. Granting, however, that 73 per cent. of both gold and silver is saved, such a result, with ore assaying \$120 per ton, would not be tolerated for any length of time in many of the outside districts; and when we consider that some 600 tons of ore are worked daily, that the tailings are the property of the mill owners, and that the mill owners manage the mines, and yet comprise but a small proportion of the owners of those mines, suspicion becomes almost certainty that a monstrous fraud is perpetrated. Six hundred tons of ore, containing over \$30 per ton, run down every day to the place prepared for it at an expense which is covered by ten days' run, will make a very nice little mine in the course of a few years—a mine which will need no miners to work it; no powder, nor drills, nor timbers, no pumps, nor hoisting machinery; a mine in which the ore will be shoveled up by Chinamen, already crushed, in which there will be no caves, nor horses, no heat, nor foul air; a mine of which the value will be accurately known, and which will therefore not be "listed," nor tossed from bull to bear, nor dealt out to "the street" at high prices, to be gathered in again, in the fullness of time, at low ones, but will be held fast in the loving embrace of a close corporation, who will work it with the greatest economy, and who will use the best obtainable process for the extraction of the precious metals; a mine that will furnish a great part if not all of the quicksilver required for its working, for those same mills are using and losing quicksilver at a very liberal rate, and are charging for it, too.

The millmen said, through their Superintendent, that they would sell these tailings—a fair proposition, doubtless, as far as it goes; they did not name the price, nor did they mention whose pockets would be the heavier for the sale. If the gentlemen alluded to really wish to clean their skirts of the imputations cast upon them, not without a show of reason, they will throw the working of the ores of mines under their control, open in good faith to public competition, and award the contract to whomever will do it for the least price, and guarantee the highest return. Dare they do this? I opine they will not; and their (defrauded?) partners are powerless.

Is it likely that this state of things would continue, or rather that such things could be done, if every stockholder had an equal voice in the election of directors?

It is idle to say that because these gentlemen own a very large interest in the mines, they have therefore a right to absolute control of the prop-

erty of their co-owners. There is no justice in such a system. Were they chosen to do so, as they would be if they showed themselves honest as well as capable, by a majority of the persons interested, there could be no objection; but they are not so chosen, they are elected by themselves with perhaps the aid of a few of their satraps and friends, and they work their imperial will with the property of a hundred times their number.

The present system of incorporations is, in its application to mining, pernicious. I know not if there is any value in my suggestions, but my purpose will be answered if should succeed in setting better heads than my own at work on a problem which is of great importance to this community, namely, how to protect the rights of share minorities (usually personal majorities) in mining companies. At present poor owners of mines are afraid to allow capital to come to their assistance, on the sole condition on which capitalists can generally be induced to take hold—that of acquiring a majority of the stock; and so the development of mines is retarded which under a better system would be made productive. ATOM.

Geology of Prospect Mountain.

EDITORS PRESS:—The elements that now form our oceans, lakes and rivers, and the gases that entered into the solid structure of our planet, once formed a dense atmosphere, impenetrable to light, enveloping the earth to a depth, not of 45 miles as is now estimated, but of thousands of miles. The best of authorities on geology inform us there was a time in the history of our planet when it was a fiery molten mass, without seas or oceans or a solid crust.

How was this thin crust formed? At this point of the investigation the geologist must appeal to the astronomer for the history of the origin and birth of our planet, for in this vague and nebulous border land, where the very rocks have no definite forms or substances and flow into each other, there the two sciences meet. Astronomy shows us our planet thrown off from the sun in a molten fiery state, to move in an independent orbit of its own. Hence arises the question, did that incandescent world contain, latent within itself, the elements of life. Structural forces lie latent in the molten mass, whether or not those forces reach to the extent of forming a planet or an animal.

Astronomy began with solid crystalline spheres. Look at the wonderful and beautiful architecture of a crystal! All the marvels of crystalline force, all those wonderful branching frost-ferns which cover our window panes on a winter morning, the exquisite molecular architecture of ice lies latent in water and comes into play when the water is sufficiently cooled. Gravitation and polarization, which blend in harmony in the working forces of the universe. Thus the teaching of science is that the world-constructing forces are latent in the mass, and that the formation of an inhabitable world is not less wonderful than the formation of a crystal. Crystallization performs an active part in the formation of the matrix, gangue or vein matter of a metallic lode. Without crystalline structure there would not be much of the precious metals in our mines, for gold and silver are crystalline.

The Geological Structure

Of Prospect mountain comprises the four great classes of rocks; the fossiliferous, volcanic, metamorphic and plutonic are all conspicuously displayed within a very small area and with their peculiar characters strongly contrasted.

The western slope contains fossiliferous limestone. On the flanks of the mountain are belts of quartzose rock and conglomerate, to which on the east side succeed belts of argillaceous shale, flanked by belts of quartzite, metamorphic limestone and other strata containing silicate of lime. The emergence of granite in the northwest spur of Prospect mountain at the surface until it has become exposed to view, is an intrusive rock of later date than the other, and bears from the Windsail shaft, (Eureka Consolidated Mining Co.) west-southwest 300 yards. This granite is underlying Ruby Hill and sends out dikes of porphyry or spurs of the granite mass itself; one of these is known to exist about one and a half miles north of the Richmond mine.

It is not difficult to form a true idea or a precise method of granitic uplift, whereby the fossiliferous limestone of Prospect mountain became shaped into a dome or arch of 12 or 14 miles long and an altitude of 7,000 or 8,000 feet above the sea level. This mountain, as seen from a distance east or west, has the dome or arch shape of the jurassic or cretaceous period, and by the testimony of a little fossil shell of the sea characteristic of the cretaceous period, the bivalve of the clam or cockle species, demonstrate the fact that Prospect mountain was at one time as low as the ocean. There are at least three

Well Defined Parallel Metallic Belts

Running nearly northwest and southeast, represented in the vein system of Prospect mountain, the lodes of Secret canyon, on the South Ruby hill, and Adams hill on the north yielding gold, silver and lead. The age or origin of the fissures of Ruby hill is precisely the same as the

SCIENTIFIC PROGRESS.

On Mineral Veins.

We find in the proceedings of a late meeting of the London Geological Society, a discussion on mineral veins opened by W. Morgan:

He maintained that no one theory can be accepted in explanation of the formation of mineral veins, and that whilst in some cases their formation may be due to the presence of pre-existent fissures induced by shifting of the containing rock, in others any such explanation is insufficient, as he thought the means by which the sides of such fissures were kept apart could not be easily indicated. The point upon which he especially insisted in connection with this question was the presence of "horses" in many mineral veins. He advocated the view that the walls of veins were in close proximity in their earliest stage, and that the enlargement and infilling of the veins took place simultaneously, by the segregation of materials derived from the adjacent rock, supplemented, perhaps, by a tension, or tendency to separation, caused by slow contraction of the latter. Instead of a fissure he assumed the presence of an irregular surface of least resistance, or of electrical action, at which the vein matter might collect at first as a mere film. In this way, he thought, the vein might increase, and its walls might recede, simply by the aggregation of the vein matter itself, and in general proportion to the degree of mineral saturation of the adjacent rocks.

Professor Ramsay said he was startled, but not terrified, by this new view of the formation of mineral veins, and especially by the implied supposition that the rocks on either side of a mineral vein were in a less consolidated state when the vein was formed than at the present time; but at the same time, considering that so many veins are to be found in deposits, which had not only been consolidated, but had already undergone metamorphism, producing slaty cleavage (as, indeed, had been mentioned by the author), before the formation of the veins contained in them, he could not altogether accept the new notion. He remarked that joints in rocks, especially limestones, are always permeable by water, and by this means fissure joints may be easily widened. Hematite, as is well known, lies in great water-worn fissures and caverns in the carboniferous limestone of south Lancashire; but with slaty rock he thought the case may be very different. He referred to the arrangement of mineral in veins in support of the view that their deposition took place in open fissures; and considering the solidity of the rocks before the formation of mineral veins, it seemed to him difficult to imagine how these immense masses could be pushed aside, as they must be, by the formation of small veins in the manner suggested by the author.

Professor Hughes mentioned cases in which protuberances had held rock faces apart during movements, as *e. g.* on a small scale, where worm tracks on the face of a Cambrian rock had given rise to a kind of crag-and-tail during movements producing slickensides along the bed on which they occurred. On a large scale, as *e. g.* in the Via Mala in the Alps, wavy fissures might be seen running down the side of the precipice; and obviously, when displacement took place along such cracks, the two sides could not be in contact along their whole length, until the protuberances had all been ground down, forming what he called "fault breccia." He thought the manner of occurrence and alterations of various minerals showed that they had been formed by crystallization along successive layers on each wall of the fissure, the growth of the crystal being outwards from the walls, and each new layer having the impress of that on which it was thrown down.

THE NEW STAR.—Prof. C. A. Young, of Dartmouth college, describes the coming of a new star in the *Journal of Chemistry*. On the evening of November 24th, 1876, Prof. Schmidt, of Athens, distinguished for his researches upon variable stars, observed in the constellation Cygnus a new star of the third magnitude, which by midnight was well up toward the second. On the 20th, the last clear night preceding, no such star had been visible. He immediately telegraphed the discovery to Paris and Vienna, but the weather was very unfavorable, so that no observations could be made until December 2d, when the star had already fallen to the fifth magnitude; by the 12th it had become invisible to the eye,—of the seventh magnitude according to Hind,—and it is now (January 10th) not above the eighth. The position of the star is near L. Cygni, in right ascension 21h. 36m., 50.4s., and in north declination 42° 16' 38.5", where none of the catalogues indicate any star at all; so that hitherto it cannot well have been brighter than the eleventh or twelfth magnitude.

A POSSIBLE NEW METAL.—Prof. G. A. Koenig, of the University of Pennsylvania, announces that he has reason to suspect the existence of a new metallic element in a mineral resembling schorlamite, occurring at Magnet Cove, Arkansas. In an examination of this mineral, he obtained, instead of titanic acid, a white oxide which differed very decidedly from the former. He is disposed to regard this circumstance as pointing most probably to the existence of a new metal in the mineral in question.

The Oldest Plant.

At a recent meeting of the Academy of Natural Sciences of Philadelphia, Mr. Martindale exhibited some specimens of the sensitive fern (*Onclea sensibilis*) in the curious condition known as the variety *obtusilobata*. The matter is of great interest, from the fact that this fern is perhaps the oldest living floral organism on the globe. It is found in a fossil state, and some paleontologists believe it has been in existence for 500,000 years. On some of the prevailing theories of evolution it ought to have branched off, by "gradual modifications," into numerous descendants, and we ought to have allied species, if not allied genera. But not only are there no very closely allied genera, but only this one single species, and it shows no tendency to produce the slightest variation worth speaking about. If we could find a good substantial variation in this fern, it would be, therefore, a case of considerable interest. Dr. Asa Gray, in his "Manual of Botany," regards the so-called variety *obtusilobata* as no variety, but as a peculiar morphological condition of the same thing; and the specimens found by Mr. Martindale perfectly confirmed this view. The male frond of the *Onclea* is but the female frond contracted and rolled up, as is the case in all ferns having the female fronds of a different character to the male. In the variety *obtusilobata* the sporangia are borne on a flat frond, like as in *Aspidium*, the lobes of the frond not rolling completely up, as in the perfect form. It is the same thing, with only the frond not as perfectly transformed. The sensitive fern ("sensitive" from its withering so soon after gathering) is also of interest from its being as "highly organized," notwithstanding its great age, as any fern of a much more modern origin, geologically speaking. There is, doubtless, much to sustain the theory of a gradual progress from a simple to a complex structure through the course of ages, but the *Onclea* is surely not among these facts.

THE MAGNET IN SURGERY.—A curious experiment was tried recently on the son of Sir Benjamin Brodie. The lad had contrived to break a needle in the calf of his leg. He was taken to the Royal Institution, in London, and a powerful electro-magnet was used to detect the position of the needle, and the possibility of moving it. The exact position was indicated by the disturbance of a magnetized needle, but no change could be produced in its position. After the experiment, however, the limb could be moved about, the pain having ceased; and, finally, the broken needle having shifted to the other side of the leg, as was shown by the index attached to the magnet, it came sufficiently near to the surface to be extracted. The experiment, though giving a negative result so far as "drawing" the needle was concerned, was so far satisfactory that it enabled the lad to use his leg without pain.

LEVERRIER ON ULTRA-NEPTUNIAN PLANETS.—After a long-continued labor Leverrier has at length, with the theory of Neptune and Uranus, completed the study of all the members of the solar system. His chief object was to decide the question whether there is an ultra-Neptunian planet, which might be detected, as Neptune was, by the perturbations produced by it on planets already known. The conclusion is negative; there is nothing indicating the existence of a body outside of Neptune. Now that there is nothing to be hoped for in the way of discovery at the outer boundaries of the solar system, we presume Leverrier will devote himself to finding the intra-Mercurial planet or planets, in whose existence he still has unshaken belief.

THE LIEBIG MONUMENT.—The sum of 140,000 marks (about \$35,000) having been collected for the Liebig memorial, the committee has decided to close the subscription list. A discussion about the site of the projected monument has arisen between the rival committees of Giesen and Munich, the former claiming the statue on the ground that from their university Liebig's fame first issued to the world; the latter because their city was subsequently the scene of his labors. It has been resolved that both towns shall have a similar memorial, and that these shall be cast in bronze, the sum collected sufficing to cover the expense of both.

ELECTRIC LIGHTING.—*Dingler's Journal* says that a new electro-magnetic lighting instrument has recently been described by M. Hess. It consists of a chromic acid element, a small induction coil, and a vessel containing a mixture of alcohol and sulphuric ether. The pressure of a knob puts the zinc of the element in contact with the liquid, and the small induction sparks inflame instantaneously the vapors of ether liberated from a sponge, which has been dipped in the mixture of alcohol and ether. According to the inventor, this instrument has the advantage of lasting a long time without requiring any attention.

NEPTUNE THE MOST DISTANT PLANET.—After a long-continued labor, M. Leverrier has at length, with the theory of Neptune and Uranus, completed the study of all members of the solar system. The author's chief object was to decide the question whether there is an ultra-Neptunian planet, which might be detected, as Neptune was, by the perturbations produced by it on planets already known. The conclusion is negative; there is nothing indicating the existence of a body outside of Neptune.

MECHANICAL PROGRESS.

Boiler Shell Drilling.

We recently gave a description of a machine made in an Eastern State for bringing the steam drill to bear upon boiler shells, instead of making the rivet holes with the punch. We now read that the English have contrived a machine for the purpose, which is thus described by *Iron*: The boiler shell may be conveniently slung by chains in a vertical position between two pairs of headstocks, carrying horizontal drills, so that the transverse joints may be all drilled by rotating the shell as each hole comes in succession between the headstock drills. The two double headstocks are carried on a traversing horizontal bed to enable them to slide closer or apart as required to suit the varying diameters of boiler shells, by means of independent rack and pinion gear. Each headstock is supplied with two drills, one of which is for drilling the holes, viz., from the outside of the shell, and the other, from the inside, is for countersinking. The inner headstock also carries two crutches or prongs, against which the boiler shell presses when the drill is brought home to its work.

The drills are driven by bevel gearing from upright spindles in the hollow headstocks, which again are driven by the horizontal shaft running along the bed-plate. The piercing drill has a self-acting feed, but has also a hand-wheel by which it may be quickly withdrawn as soon as the plates are pierced.

After the piercing drills have completed their part of the work and are withdrawn, the countersinking drill is brought up to its work before the position of the shell is moved. The countersinking drill is kept there by the action of a hand-treadle lever, carried to the side of the machine and outside the boiler shell. This places them handily for the operation of the machine hand.

When the boiler has been duly slung and set for a ring of holes, which may easily set out by template, the drills may be attended to by two laborers, and the holes rapidly drilled and countersunk ready for riveting up. There is thus no drifting of the holes required. The work turned out by these machines, though cheaply done, should thus be of the very highest character for accuracy and strength. At the same time the simplicity and easy working of the tool will make it a favorite in the workshops, being within the skill of any laborer. This machine has already been tested and approved in one of the principal boiler-maker's shops in Lancashire.

Testing Tension on Iron Rods

A writer for the *Railroad Gazette* submits for the consideration of engineers having charge of the erection and maintenance of railroad bridges, the subjoined suggestion of a plan for enabling the bridge inspectors to determine whether or not each rod under tension in a bridge has been properly set up in the erection of the structure; and at any time afterward whether or not each such rod is doing its duty.

When a bridge is about to be set up, let one rod out of each lot of a certain length and diameter be suspended at one end and loaded at the other end with an actual weight equivalent to the strain that every rod of that length and diameter ought, according to the calculations of the designer of the bridge, to be subjected in the structure when ready for the imposition of its live load. Then put upon the rod, with white paint, a ring, at, say, five feet above the highest point at which the rods will be held in the angle-blocks, on the lower chord of the bridge. Then provide a steel hammer of a known weight, fitted with a handle of a known length, and as many tuning-forks as there are sizes of rods in the bridge. Then with his left hand, with his left arm fully extended, let the inspector hold a tuning-fork firmly against the rod at the painted ring, while with his right hand with the arm fully extended, he strikes the rod at the ring, a smart blow with the hammer. Then, immediately removing the tuning-fork, let him note the sound given out by the rod and the fork respectively, and by filing the fork bring the fork into tune with the rod. Then let a designating number be stamped upon both rod and tuning-fork; and repeat the operation for each set of rods in the bridge. Thereafter, when the bridge is set up, and still thereafter, when the inspector is to go through that bridge, he will take the hammer and set of tuning-forks belonging to that structure, and tune his rods. Thus he may guard against, or detect the condition too frequently existing in bridges, under which some rods are unduly strained and some others are doing almost no work.

AN ATMOSPHERIC LOCOMOTIVE ENGINE.—An atmospheric locomotive engine, designed by Major Beaumont, Royal Engineers, has been on trial at Woolwich arsenal for some time past, and appears likely to be attended with success. The apparatus consists of a large number of elongated cylinders—about 70 in all—piled together in an oblique stack, each cylinder being some four inches in diameter and about six feet in length. Mounted on an ordinary truck, and by the ordinary crank arrangement, the compressed air stored in the cylinders has been found to exercise power sufficient to draw a light load for a considerable distance, and to keep up speed for a long time before requiring to be replenished.

Portable Steam Engines.

The increase in the use of steam, and consequently in demand for mechanic's work, by the spread of portable engines, is great. There have been many valuable inventions to adapt these engines to the consumption of different kinds of fuels. We read in a book on the portable engine just published in England that the absence of fire-wood and heavy cost of coal on the steppes of Hungary and south Russia appears to have almost excluded the use of steam in those districts, until the application of straw and other vegetable substances as fuel became known. The want of steam power is equally felt in other agricultural districts besides those already mentioned. In India the dried leaves of fibrous plants, the scrub or brushwood, and the stalks of the cotton plant supply an excellent substitute for coal in boilers properly constructed. In Egypt the cotton plants are pulled up after having attained a certain growth, and the stalks, which are about one-half inch in diameter and four to five feet in length, contain all the calorific properties of good wood, and will burn perfectly well if properly inserted into the furnace. In the large wheat-growing districts of the Maremma and the Puglia, in the west and south of Italy, wood and coal are very scarce, and as the grain requires to be threshed very shortly after harvest, on account of the nature of the climate, the farmer would gladly avail himself of steam power provided he could use his straw, which he has always at hand and in superfluous abundance. In South America, New Zealand and the extensive prairies of the River Plate, Chile and Mexico, the universal demand of the farmers is for steam machinery which can be worked with indigenous fuel; and the time may come ere long when the land in these countries shall be plowed, the crops harvested and threshed, and the grain ground into flour by steam engines fed with straw, brushwood and vegetable refuse grown on the estate. But the great recommendation of some improved portable engines appears to be that with slight changes in the arrangements of the fire bars they will burn not only coal, wood and the various vegetable substances already enumerated, but also peat of all kinds, sawdust, chips and megass, the refuse of the sugar cane, and, in fact, almost any vegetable refuse within reach. There can be no question that the adoption of this class of engine would permit of the introduction of steam power in almost innumerable localities from which it has hitherto been excluded, and as all the fittings attached to it are of the best and most approved form, it may be hoped that its use will be widely extended.

Narrow-Gauge Progress.

The *Railway Age* has the following figures on the progress of narrow-gauge railroads, which is a matter of interest in many counties of this State: Narrow-gauge building on this continent may be said to have begun in 1871, only six years ago, and its progress may be noted as follows: 1871, miles of narrow-gauge built, 179; 1872, 450 miles; 1873, 555 miles; 1874, 819 miles; 1875, 585 miles; 1876, 569 miles. Total in operation in America, 3,157 miles. These figures are nearly correct, though, probably, not entirely complete. This shows an addition of 569 miles of narrow-gauge track in twenty-one States—more than one-fifth the total number of miles of railway constructed in the country during the year, according to most authorities. For a system practically of recent introduction and which is still considered by many of doubtful economy and efficiency, this certainly is a very encouraging showing, and indicates that, in spite of the assertions of some that narrow-gauge roads will not and must not be built, they have been and will continue to be built. The thirty-three roads whose extensions are noted above have now a total length of nearly 1,000 miles, and this is less than one-third of the total narrow-gauge mileage now in operation in America. The number of narrow-gauge roads in operation in America is over 100, besides an indefinite number projected.

ENGLISH FEAR.—The *Iron Age* says: English manufacturers look with little cordiality on the French exhibition of 1878. The London papers say "the world is tired of exhibitions." The fact is that they dread another competition with American manufacturers in the presence of the world. Their defeat at Philadelphia is well understood in Europe, and is hurting their foreign trade, and another such at Paris in 1878 would be likely to prove a serious blow to British industries.

ELECTRIC CLOCKS IN PARIS.—For making the four electric timekeepers which the city of Paris intends to erect, 15 names have already been entered. The competition will close on September 30th, 1877. The four clocks finally selected will be bought by the city of Paris at £200 each. Three prizes, £120, £80, and £40, will be allowed respectively in addition for the three best clocks.

PENSION TO AN INVENTOR.—The Societe d'Encouragement Nationale has been petitioned on behalf of the inventor of the pneumatic lever, Mr. Barker, who has resided in France for some time, and has made in that country the discovery of the above mentioned lever, and of the method of applying electricity in aid of organ playing. An international committee was formed for purchasing an annuity.

Continued from page 98.

series of Prospect mountain. The dynamical cause is the same for the reason that those parallel to each other were formed at the same time, and the age was that of axis of uplift. The Richmond mine, the first in present productiveness and among the first in richness of the argentiferous and plumbiferous deposits of the State of Nevada, is a contact vein (and not, as is erroneously called, a pipe vein). Contact veins are those whose walls are formed of dissimilar rocks. Situated on Ruby hill, a spur of Prospect mountain, the strike of the lode is nearly northwest and southeast magnetic, and dips northeast.

The Mines.

Next to the Richmond in point of present importance is the Eureka Con., being a part of the same lode, and has much the same strike and dip as the Richmond has. The K. K. is next, apparently on the same ore channel. The Jackson, a little south of the K. K.; the indications at the opening of this mine promised a bright future. It seems there are vicissitudes in the working life of a mine similar to that of a prospector, who, after battling a long time against the ebb tide of fate, suddenly becomes rich through the flood tide of fortune flowing in his favor, and again, after a short and reckless career, becomes suddenly poor. Such has been the experience of the Jackson company. Under the present efficient managers this mine will soon become one of the productive mines of Eureka county.

Prospect mountain is not complete, is not finished yet. Those remorseless and inexorable forces that made it what it is are still at work making it what it is yet to be. The winds and rains, the heat, frost and snow are doing their work in denudation and disintegration.

JOHN M. FOLEY.

Eureka, Eureka Co., Nev., Feb. 5th, 1877.

Globe District, Arizona.

EDITORS PRESS:—The following is the latest mining and metallurgical news about Globe district, Arizona:

The Garish smelting works, situated at the Wheatfields, started up last week. Up to the present time (January 26th) they have turned out considerable copper, which assays about 90% in fineness. The copper contains a large percentage of gold and silver. They estimate the crude bullion to be worth \$1,000 per ton. They will start smelting silver ores next week. The Wheatfield milling company have completed their ditch, and intend to have their mill running in 60 days. It is a complete California quartz mill. The Richmond mine, at Richmond basin, is looking splendid; shaft, 25 feet deep; vein, three feet wide. Ore milled at Morrill's mill \$2,700 per ton. Mr. Stiles has been offered \$30,000 for his half, but he would not sell. In the McCormick extension the shaft has obtained a depth of 76 feet, where the vein is four feet wide, well defined and average assays made go over 400 ounces per ton. They are getting out ore to have milled. In the Stockman mine sinking the shaft is going rapidly ahead. The shaft is being well timbered. At 30 feet they have got a six-foot vein, with an 18-inch streak of ore that assays high. In the Kentuck mine, at 35 feet, the vein is over four feet wide. The ore is what is known as copper silver glance. The ore worked over 3,000 ounces to the ton. There is four feet solid of that kind of ore. The Barney claim, owned by J. M. Barney, of Yuma, is turning out over \$1,000 a day. It is situated in Richmond basin, and the ore is found in a horizontal strata. Over \$15,000 has been taken out within these last couple of weeks. The Champion mine is looking better than ever before. The owners have let a contract to sink 100 feet. When the shaft is completed they will commence taking out ore. At present they are working up the dump piles. In sinking a shaft on the Munson mine, they struck a very rich body of ore that don't need to be assayed to tell what it contains. The vein in bottom of shaft of the Lazy Bob mine is looking good. The shaft is 40 feet deep; vein, two feet wide; character of ore, copper silver glance. The result of a working test shows the second-class ore to contain 580 ounces to the ton.

The following variety of silver ores are to be found in the Globe district: Native silver in cubic crystals, iodide of silver, bromide of silver, chloride of silver and selinite of silver, brittle silver ore, silver glance, polytasite, miargyrite, proustite and stromeyerite. T. P. G. Globe City, A. T.

SONOMA QUICKSILVER.—The productive quicksilver mines of Sonoma county are the Oakland, near Geyser peak, producing about 300 flasks a month; the Cloverdale, on Sulphur creek, producing 160 flasks; the Great Eastern, near Guerneville, producing 125 flasks; and the Mt. Jackson, near the Great Eastern, producing 100 flasks. Total production, 625 flasks per month. There are other mines that could be made productive with little work, but the owners do not care to work them at present prices.

HELIUM is a hypothetical solar element, indicated by certain spectrum lines that cannot be referred to any known terrestrial element.

Reed-Birds, or Bob-o-Link.

Our illustration shows members of the feathered tribe which comes from the Atlantic shore, both north and south, will recognize. It is known as the "meadow-bird" in Louisiana, the "reed-bird" in Pennsylvania, the "rice-bunting" in the Carolinas, the "bob-o-link" in New York and thence eastward; is always the same, and yet of very different characteristics in the different regions. Entering the southern portions of the United States, it proceeds northward in early spring, flying by night; but, returning in the autumn, it flies by day. It reaches New York by the middle of May, having inflicted much injury upon the corn-fields of the South in its journey, but is believed to do little injury in the North. At this season it becomes so plentiful all over the country as to be found in pairs in every corn-field and meadow, their varied plumage and joyous song everywhere attracting the desires of bird-catchers, who capture them in trap-cages, and sell them

nate between birds that are beneficial and birds that are injurious. In making up his estimates of the horticultural value of the different species of birds, he bases his calculations upon the following guiding principles:

First. Any bird of which it is only known that it feeds upon insects, is to be regarded as beneficial, until facts are discovered to the contrary.

Second. A bird feeding upon *Hymenoptera* (bees, wasps, ants, etc.) is to that extent probably injurious. A bird feeding on ants is to that extent neutral, neither beneficial nor injurious.

Third. A bird feeding upon *Lepidoptera* (butterflies and moths) is to that extent probably beneficial; if this is a twilight bird it is almost certainly so.

Fourth. A bird may be reckoned beneficial, in so far as it feeds upon caterpillars with two rows of abdominal prolegs.

Fifth. He can infer little or nothing, at present, from the presence of *Diptera* (flies, gnats, etc.) in a bird's stomach.

THE REED-BIRD, OR BOB-O-LINK.

for good prices in every city. They are sometimes taken to Europe, and, in such cases, the change in the hue and the cessation of the song of the male, by the time the journey is over, often disappoints the adventurous shipper. In captivity they are easily tamed, but appear cheerful only in spring and parts of the summer, though the song is never so glad as when the bird is free.

Our illustration calls to mind the somewhat vexed question of the value of birds to the agriculturist. It is well known that while there are birds which play havoc with crops of grain and fruit there are also birds which wage a valuable warfare upon noxious insects. There are also birds which divide their attention between fruit and insects and some which seem to be most fond of eating insects which are known to be beneficial. It is quite proper that scientific investigation should be brought to bear upon the actions of birds to ascertain their value or worthlessness. We learn from a Chicago exchange that Professor S. A. Forbes, of Normal, Ill., has been engaged in a work of this kind. He is examining the stomachs of the different species of birds (he has 1,000 stomachs already gathered and preserved in alcohol for this purpose), to ascertain the kinds of food on which they live, and to gather facts, so as to be able to discrimi-

Sixth. *Coleoptera* (beetles), considered in the mass, are to be reckoned injurious. *Cicindelidae* (tiger beetles), *Carabidae* (ground beetles), *Coccinellidae* (ladybirds), *Lampyridae* (fire flies), are beneficial. The *Cerambycidae* and some *Meloidae*, the tetramerous beetles, are especially injurious.

Seventh. *Orthoptera* (cockroaches, crickets, grasshoppers, etc.) may be set down as injurious. Many of those species which are not now especially beneficial would become so if their increase were unrestrained.

Eighth. A bird feeding upon small *Neuroptera* (dragon flies, lace wing flies, may flies, white ants, etc.) is of suspicious character.

Ninth. *Myriapoda* are on the whole beneficial. *Chilopoda* especially so, while *Chilognaths* are neutral.

Tenth. Spiders are beneficial, and birds eating them largely are to be watched. The *Phalangidae* (harvestmen) are especially to be protected.

Upon the above classification the stomachs of the birds are examined and their probable value or injury determined. It is also announced that Prof. Forbes, assisted by Prof. Cyrus Thomas, State Entomologist, contemplates the preparation of a bill, to be submitted to the legislature of Illinois, having in view the promotion

of economical science. The object is to secure a small appropriation, say \$2,000, for the investigation of the food and habits of birds, with reference to their relation to agriculture and horticulture, also to study the food and habits of fishes, with a view to ascertain the condition essential to the increase and propagation of the kinds most valuable for food, and also for the collection and preparation of specimens of the injurious and beneficial animals of the State, especially birds, fishes and insects, to be placed in the State House at Springfield, and also in the museums of the various State educational institutions. It is not proposed to pay any officers' salaries with the money, but only to pay the actual expenses of the work.

From the above movement in Illinois we may take a hint for useful scientific work, for with the rapid spread of noxious insects in this State it seems clear that early precautionary measures will be wise on the part of our legislators.

Reese River Mines.

In view of the wonderful success attending the operations of the Manhattan company, it seems almost beyond belief that fifty per cent. of the valuable quartz veins lying within a mile's distance of this office are not only allowed to remain idle, but are absolutely open to location. With the exception of the energetic, well-directed and successful efforts of the Manhattan company, and the operations now being conducted by the King Alfred company, and the persistent efforts of the Pacific company, of London, the work of developing our mines is now confined to the individual efforts of poor miners, whose operations are necessarily limited by the slender means possessed, and whose workings are frequently entirely suspended for long periods, during which day's pay is obtained from other sources in order to secure means with which to continue prospecting.

There is not a more extensive or inviting field for the investment of capital on the face of the globe than that presented by the idle quartz veins of Lander hill and vicinity. In Marshall canyon, to the south, there are numerous ledges of from one to ten feet in width open to location, which only require the performance of a moderate amount of work in order to be made immensely remunerative properties. It was in this canyon that the Whitchell Union company's ledge was situated, and which yielded fabulous wealth to its owners. Descending the northern hill forming this canyon, we reach Lander hill proper, upon which are situated the principal mines owned by the Manhattan company, which have yielded their millions in the past, and are now paying their owners magnificent profits, and, judging from present appearances, will continue to do so for all time to come.

Upon this hill, in addition to the Frost, Curtis, South America, Bowman, Oregon, North Star, Ogden, Mohawk, Dollarhide, Eclipse, Esther, Savage, Toiyabe and Sherman, all of which splendid mines, with their well appointed hoisting works, are owned and worked by the Manhattan company, are also situated many other valuable mines owned by other companies; among them may be mentioned the mines of the New Pacific mining company, limited, of London, which under the present efficient, economical and energetic management, promise to become very valuable properties. Within the past few months two splendid ore bodies have been developed, the exact location of which we have been unable to learn, but we are assured by the intelligent although reticent gentleman in charge, will more than reward the laborious efforts of past years and fully meet the expectations of his English employers, and that although unlooked-for difficulties have prevented the company from realizing from developments made up to the present time, yet the work of ore extraction is now in a fair way of commencement, ore shipments to the Manhattan mill will soon be made and regularly continued for a long time to come. The present manager of this company's affairs has had many difficulties to encounter, and it will please his numerous friends to learn that his perseverance has been attended by success. Of the ore developments mentioned we know only by hearsay, but the Superintendent smilingly told us in a very confident way, "that his friends had helped him and his company a great deal, but that his ore would help both a great deal more."

Adjoining the Pacific mine, on the west, is the Florida, and west of that is the Magnolia, owned by our esteemed fellow townsman and ex-mayor, Wm. H. Clark. A splendid ore body has been struck in this mine, and its lucky owner is more than ever convinced of the inexhaustible wealth of Lander hill.

It is our design to call the attention of capitalists and others to our undeveloped mineral wealth, and with this object in view we make this the introductory to a series of articles to be published from time to time, descriptive of mines and ledges in this vicinity. Our next article will contain the results of observations made in Emigrant canyon, and, if obtainable, an account of operations now being conducted in the King Alfred mine.—Reese River Revue.

A BIG BAROMETER.—A large barometer has been set up by M. Redier at the church of St. Eustache, Paris. The total diameter is exactly six feet, inclosing a dial five feet wide, lit at night by an inner corona of eight gas-jets. The hand measures three feet six inches in length, and is moved right or left by wheelwork, which follows the variations of a small aneroid barometer, which regulates the instrument.

The Pittsburgh Mine.

On visiting the Pittsburgh the other day we found a very satisfactory condition of affairs. The mine is under the superintendence of Capt. White, one of the oldest and most experienced miners of the State, and is owned by a San Francisco company, who purchased directly after the hoisting works were burned on its last year. The company have erected a new building since, and had moved into place an extra engine, which was formerly used for hoisting at the shaft near the mill. They have also made general repairs at the mill, have pumped out the mine which had filled up while lying idle, and have been running drifts and other underground work. About 115 tons of rock have been taken out since the drifts have been opened, most of which has been put through the mill. Judging by the amount of amalgam taken off from the plates, it was estimated by the superintendent that the average of the lot would not fall short of \$24 to the ton in free gold. The ledge in the north drift runs from eight to 24 inches in width. The rock is the best where it is the smallest. The mill has 10 stamps, and the usual appliances for saving gold and sulphurets. The sulphurets vary in value from \$113 to \$160 to the ton. There are employed at the mine and mill at the present time, 26 men. To thoroughly open the mine so that it can be worked to the best advantage, and to insure regular dividends, it is necessary that the incline should be sunk from the 700-foot level, and that considerable dead work should be performed. It is thought that \$10,000, with the proceeds of the rock taken out while the dead work is being done, would place the mine in a first-class working condition. A miner who worked in the Pittsburgh seven years under former proprietors, informs us that, in his opinion, it is the best mine in the county if properly opened and worked. We hope to see the necessary outlay made so we can be able to add the Pittsburgh to the list of regular dividend payers, and from all we can learn, we think such will be the case in the near future.—*Nevada Transcript*.

Expensive Tunnel Developments.

In order to secure an outlet and fall for the debris washed out in the process of working on hydraulic mining claims, long and expensive tunnels through hard rock have to be run. Several such enterprises have been completed in this county during the past two years, which show the magnitude of our mining operations. On the San Juan ridge, we find in a recent report the following memoranda concerning several such works, which we give to our readers: The Boston tunnel, on Woolsey's flat, is 1,600 feet in length, and cost \$40,000. The North Bloomfield tunnel, at Humboldt canyon, is 3,000 feet in length, and cost \$500,000. The one run into the American mine, at San Juan, is 3,900 feet long, and cost \$140,000. The one at Sweetland, which was run in to tap the Manzanita mine, is 1,740 feet long, and cost \$62,000. The Sweetland creek tunnel is 2,200 feet long and cost \$90,000. The French Corral mine has been tapped by a tunnel 3,500 feet long, which cost \$165,000. There is one being run at Badger Hill which will be 1,400 feet long, and one below Sweetland which will be 2,600 feet long, both of which are not yet completed. The ground owned by the Eureka Lake company, located at North Bloomfield, will before long be opened, and it will require a tunnel in the neighborhood of 3,000 or 4,000 feet in length. There are several bedrock tunnels being run in other parts of the county. Many claims on the old river channels are located so far from a proper outlet that they have to be worked by drifting. Inclines are being sunk in several places to get down to the bedrock on such claims. From the large number of such enterprises now on foot, in connection with the tunnels and shafts completed during the past two years, we feel justified in predicting that the gold yield of the county will soon begin to show a large increase over past years. While this gratifying state of affairs exists among gravel mines, the quartz interest is not lagging. Many new and valuable mines have been opened the past year, and developments are being made on a large number of new ledges, which promise first-rate. The county's prospects for the future were never better.—*Nevada Transcript*.

A RICH STRIKE.—In the Behm mine, Mountain lode, at a depth of about 50 feet, a rich shute of copper ore—probably the richest that has ever been found in the camp—was met with a few days ago while sinking down the shaft. The vein matter at this point is about three feet wide, consisting of copper glance, red and black oxide. Of the latter a streak of from 12 to 18 inches wide runs through the vein, and is of a very high grade, assaying nearly 75 per cent. copper. About two tons of this ore has already been taken out, and as work is steadily progressing upon the shaft, the out-put will continue steadily to increase. A specimen of the ore mentioned can be seen at our office, and as its richness is so great as to make it a very desirable commodity for shipment, this find should stimulate all those owning claims upon this lode to push forward the work of development in hope of coming upon a similar deposit. The owners of the Behm mine are to be congratulated on their success, for they have had much to contend with and many discouragements to face while prosecuting work upon their claim to its present development, and we trust that they may reap the full reward of their labor.—*Butte (Montana) Miner*.

USEFUL INFORMATION.

TO TAKE OUT GLASS STOPPERS FROM BOTTLES.—Amateurs are often troubled to do this in obstinate cases, and will be grateful for the following practical hints on the subject, condensed from the *Druggists' Circular*: When only water has been in the bottle, the best way is to apply heat to the neck of the bottle. To do this successfully, without breaking the bottle, the wick of a spirit lamp is trimmed so as to give a flame of about the size of the neck of the vial. The bottle is held in the flame with the two hands and turned as rapidly as possible, while its neck is immersed in the middle of the flame. From time to time the vial is taken out of the fire, and the stopper tried. If it holds fast, the bottle is heated again, without loss of time, until the stopper comes out; then bottle and stopper are allowed to cool separately. The whole operation takes generally from four to ten seconds. In skillful hands it is invariably successful in less time than it takes to explain the manipulation; but beginners, through injudicious heating, generally break the first bottles which they try to open. When the bottle contains other liquids than water, it is necessary, before applying heat, to dissolve out any substance that may have dried between the stopper and the neck of the bottle. To effect this, the bottle is inverted in a small graduate containing the appropriate solvent, that is, water for sugary liquids or other soluble substances, alcohol for resinous bodies, etc. After six or eight hours, the stopper is frequently found unloosened without the use of other means. By the way, the heat is applied as rapidly as possible, because it is important that the neck of the bottle should become warmed, and thereby dilated, before the stopper has had time to expand also. In some cases it is impossible to open the bottle at all without breaking it. This happens when it contains or has contained alkalies, their carbonates, etc., which completely solder the glass together. It is almost unnecessary to add that alcoholic and ethereal liquids require the exercise of the utmost caution, to avoid accidents.

TIN-FOIL.—It may not be generally known that tin-foil, as now so widely used in the trade, is not a foil made of tin alone, but composed mainly of lead with but a slight alloy of tin. The manifold appliance of tin-foil to articles of consumption and medicine is not regulated with us by any law such as exists in European countries, forbidding the use of lead or composition, or otherwise impure tin-foil in all cases where it may, through oxidation or contact with the goods, become poisonous and injurious to the health of the consumers—as is the case in some instances. Too little attention has been paid to this subject so far. It is to be hoped that ignorance, and not wilful oversight of the facts, has led many manufacturers and dealers to use an article accompanied with such risks, for the sake of saving a trifle in the cost. Besides this saving is, in most instances, imaginary, as the German pure tin-foil combines such a fineness and large yield, with relatively great softness and strength, that it will practically answer most purposes, and not cost more than an equal surface of the lightest composition foil, while all heavier grades of the latter will be much more expensive to use. The yield of the regular German pure tin-foil is 72 square feet, or 10,368 square inches per pound; a heavier grade yields 66 square feet. The sheets are large-sized and waste in cutting is consequently small.—*New Remedies*.

MUMMIES CONVERTED INTO PAINT.—Few persons are aware that veritable Egyptian mummies are ground up into paints. But in this country and in Europe mummies are used for this purpose—the asphaltum with which they are impregnated being of a quality superior to that which can elsewhere be attained, and producing a popular brownish tint when made into paint, which is prized by distinguished artists both of this and other countries. The ancient Egyptians, when they put away their dead, wrapped in clothes saturated with asphaltum, builded, as it were, better than they knew, and could never have realized the fact that ages after they had been laid in the tombs and pyramids along the Nile, their dust would be used in painting pictures in a world then undiscovered, and by artists whose languages were to them unknown. That a portion of one of the Pharaohs, or a Potiphar, or even of the historic Mrs. Potiphar, may even now be on the canvass of a Veruet, a Millais, or a Church, who may question?—*Washington Gazette*.

SUNDAY TRAINS IN CANADA.—Railway trains are not to be permitted for the future to run on Sundays in Canada. The Dominion government has issued orders that no trains are to be run on Sundays, excepting in cases of great emergency. Of this emergency the authorities are to be the judge, no Sunday train being permitted except on direct government order.

ANILINE colors, according to Mr. Joseph Seidebotham, are being extensively employed for tinting photographs, and likewise in paintings and water color drawings. He calls attention to the well known instability of these beautiful tints, and warns artists who desire the permanency of their work to avoid employing them.

UTILIZATION OF SEA-WEED.—The *Quarterly Journal of Science* says: At the chemical works at Aalborg, in Jutland, Denmark, where about 30 tons of alkali are made per week by the ammonia process for obtaining alkali from sea-weed, Mr. Thowald Schmidt, the director of the manufactory, proposes to work, in conjunction with this process, a method devised by himself of treating sea-weed so as to obtain iodine, potash salts, and other marketable products therefrom. In Denmark a very heavy duty is levied on the importation of common salt, whilst enormous quantities of sea-weed, rich in iodine and potash, can be obtained at small cost in the neighborhood of the works. Mr. Schmidt's process is as follows: After the sea-weed is dried and burnt, a concentrated solution of the ash is made and added to the liquor containing chlorides of sodium and calcium, left after the ammonia has been recovered in the ammonia-soda process by boiling with lime. The sulphates of potash, soda and magnesia contained in the ash of the sea-weed are thereby decomposed, and hydrated sulphide of lime and hydrated magnesia are precipitated in a form which may be available for paper-making as "pearl-hardening." The last traces of sulphates are got rid of by adding a small quantity of solution of chloride of barium. To the clear solution nitrate of lead is now added until all the iodine is precipitated as iodide of lead, which is then separated by filtration and treated for the production of iodine or iodides. After filtration the liquid is boiled, nitrate of soda is added to convert the chloride of potassium present into nitrate of potash. The latter is separated by crystallization. There remains a solution of common salt containing traces of ammonia from the previous soda operation and a trace of chloride of potassium. This solution is again treated by the ordinary ammonia-soda process for the production of bicarbonate of soda and white alkali.

LOAD FOR A MAN.—A curious set of experiments made in France developed some interesting facts in regard to the greatest average load for a man of great strength to carry a short distance. This was found to be 319 pounds; all a man can carry habitually, as for example, a soldier his knapsack, walking on level ground, is 132 pounds, (an extreme load it would seem,) or he can carry an aggregate of 1,518 pounds over 3,200 feet as a day's work, under like circumstances. If he ascend ladders or stairs, as do hod-carriers, then he can carry but 121 pounds continuously, and his day's work cannot exceed 1,232 pounds raised 3,300 feet high. With regard to the effort and the velocity with which a man can produce by pulling or pushing with his arms, it has been found by these experiments that, under the most favorable circumstances, and for continuous work, an effect cannot be gained exceeding from 26.4 to 33 pounds raised from 1.8 to 1.2 feet per second, or about one-eighth-horse power.

ARTIFICIAL BEESWAX.—A mixture of paraffine and common resin has found its way into the market as a substitute for beeswax. It resembles the genuine article very closely in color, fracture and adhesiveness. The cakes are generally covered with a thin coat of genuine beeswax.

GOOD HEALTH.

Poisonous India-Rubber Toys.

A. F. Taylor, Ph. D., of Andover, Mass., sends the following note to the *Journal of Chemistry*: Prof. B. Tollens, in the *Journal of the Berlin Chemical Society*, of November 13th, 1876, calls attention to the injuriousness of many of the articles manufactured from caoutchouc, which, among other impurities, contain a very large per cent. of zinc oxide. In the rubber nipples of milk bottles for children, this has often been found to be the case, and so much attention has been called to this fact that the manufacture of these nipples containing zinc oxide has to a great extent ceased.

But more recently suspicions have been aroused concerning the quality of children's toys, dolls, animals, etc., made from rubber. One case, in which a child, having one of these dolls, had had it for some time in its mouth, grew sick, and the doll, laid in vinegar, became covered with an incrustation (without doubt zinc acetate), led to direct investigation. In 0.7325 gramme of such a doll, 0.4445 gramme zinc oxide was found, or 60.58%. Another portion gave, after being subjected to a red heat, 62.64 gramme of ash, yellow while hot, white on cooling. In the ash besides the zinc were traces of lime, iron and phosphoric acid. From another doll which had been warranted "harmless," 57.68% of ash were obtained, consisting almost wholly of zinc oxide.

It is not at all improbable that the sickness of the child, particularly the severe vomiting, was caused by the zinc oxide, and it is to be wished that the manufacture and sale of such articles containing zinc oxide could be prohibited.

PAIN.—"Pain" is an ache, or abnormal feeling, produced from an unnatural condition of the nerve or nerves afflicted, and in most cases it is induced by pressure, derangement, disintegration, or the imperfect circulation of the blood in or near them. Proof of the first and last: Rubbing over and near the sensitive nerves by increasing the circulation mechanically, will remove the annoyance.

Sleeplessness.

It is a familiar fact to medical men, says the *Journal of Chemistry*, that thousands suffer from wakefulness who are otherwise in good health. With some of them this becomes a habit, and too often a growing one. Not a few resort to soporific drugs, and the taste for opium is thus often initiated. Others find alcoholic liquors occasionally effectual, and there can be no doubt that in this way the foundation of intemperate indulgence in these liquors has been laid. Many people, however, have found a way of going to sleep without resort to such dangerous measures. For instance, looking at a fixed point steadily will often succeed in inducing sleep; or, if it is too dark to do this, closing the eyes and in imagination watching attentively the stream of air entering and leaving the nostrils. Another plan has recently been proposed by Dr. Cooke, who tells us that in many cases of sleeplessness it is only necessary to breathe very slowly and quietly for a few minutes to secure refreshing sleep. He thinks that most cases depend on hyperemia of the brain, and that in this slow breathing the blood supply is lessened sufficiently to make an impression. Certainly, when the mind is uncontrollably active, and so prevents sleep, persons whose observation was worth trusting have testified that the breathing was quick and short, and they have found they became more disposed to sleep by breathing slowly. This supports Dr. Cooke's practice, but at other times his plan quite failed. It is certainly worth any one's while who is occasionally sleepless to give it a trial. In doing so they should breathe very quietly, rather deeply, and at long intervals, but not long enough to cause the least feeling of uneasiness. In fine, they should imitate a person sleeping, and do it steadily for several minutes.

In no case should opiates or other drugs be resorted to for sleeplessness except under the direction of a physician. The other methods mentioned above may be safely tried by anybody; but if they fail, and the case becomes at all serious, medical advice should be promptly taken.

THE MORAL VALUE OF PHYSICAL STRENGTH.—The American scholar and thinker is by rule a dyspeptic. He is a razor-faced, lantern-jawed, thin, nervous man. This is partly the effect of climate, and partly that of diet and regimen. In the old days of bran bread, and prayers before daylight in the colleges, and long morning walks before breakfast, and suicidal, consumptive habits, it required a pretty tough man to live through his studies at all. We are now doing this thing better, but we have not reached the highest outcome of the change, and shall not reach it, probably, for several generations. But we have come to the recognition of the fact that it does not toughen a man to reduce his diet, to cut short his sleep, to take long walks on an empty stomach, and to indulge in cold baths when there is no well-supported vitality to respond to them. We have come to the conviction that, for a useful public life, brains are of very little account if there are no muscles to do their bidding. In short, we have learned that without physical vitality the profoundest learning, the most charming talents, and the best accomplishments are of little use to a public man in whatever field of professional life he may be engaged.—*Scribner's Monthly*.

BLUE GLASS FOR WEAK EYES.—Noted oculists in Europe recommend either blue, blueish-gray or smoke-colored glasses as a protection for weak eyes, against the unpleasant effects of red, orange and yellow light. On the same principle the trying reddish-yellow light of candles, lamps and gas on normal eyes as well as weak ones, can be pleasantly modified by the use of blue chimneys or globes, or at least of shades for the reflection of the light, colored a light ultramarine blue. A near approach to daylight is said to be produced by a petroleum lamp with a round wick and a light blue chimney of twice the usual length, the latter causing so great a draft that the petroleum burns with nearly a pure white flame.

LADY DOCTORS IN EUROPE.—The *London Medical Record* says that 40 lady medical students are pursuing their studies in the schools of the faculty, and in the hospitals of Paris, of whom fourteen are English. Of the rest the majority are Russian, and the remaining number are American, German and French ladies. Several ladies have already graduated M. D. of the University of Paris, including Mrs. Garrett Anderson, Mrs. Putnam Jacobi, Madame Bres and Madame Riband; the last three all graduated with great distinction, their theses being honorably noted by the faculty. Three lady graduates of Zurich are now practicing in England, Mrs. Hogan and Mrs. Atkinson, in London, and Mrs. Walker Dunbar in Bristol.

A CORRESPONDENT of the *English Mechanic*, in answer to a question as to the best means of keeping the feet dry in winter, says: "A simple plan would be, on having a pair of shoes made, to order the maker to put between the soles a piece of gutta percha as thick as a sixpence. No wet or damp will ever get through. I have adopted this plan for some years. Formerly I had both wet and cold feet continually, which even worn stockings failed to keep warm; now I wear cotton all the winter, and never have cold feet."

MINING AND SCIENTIFIC PRESS.

W. B. EWER, SENIOR EDITOR.

DEWEY & CO., Publishers,

A. T. DEWEY, GEO. H. STRONG,
W. B. EWER, JNO. L. BOONE.

Office, No. 224 Sansome Street, S. E. Corner of California Street, San Francisco.

Subscription and Advertising Rates.

ADVERTISING RATES.	1 week.	1 month.	3 mos.	12 mos.
Per line.....	25	80	\$ 2.00	\$ 5.00
Half inch (1 square).....	\$1.00	\$3.00	7.50	24.00
One inch.....	1.50	4.00	12.00	40.00

Four weeks are rated as one month. Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing in extraordinary type or in particular parts of the paper inserted at special rates.

Subscription in Advance.—Postage paid—one year, \$4; six months, \$2.25; three months, \$1.25. Remittances by registered letters or P. O. orders at our risk.

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription.

THE ORIGINAL ARTICLES in this paper are mostly set in solid type, giving in our columns one-third more reading than is contained in ordinary leaded matter.

Address all letters to the firm, and not to individual members, or others, who may at any time be absent.

Our latest forms go to press on Thursday evening.

SAN FRANCISCO:

Saturday Morning, Feb. 17, 1877.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—A Home for the Sailors; Scenery on the Columbia River, 97. An Automatic Amalgam Saving Machine; Expenditures on Claims; Items of Interest from the Mines, 104. "Short-Cut" Method of Describing Gear Teeth; Mechanical Ore Concentration and Separation, 105. Notices of Recent Patents; Patents and Inventions, 108.

ILLUSTRATIONS.—San Francisco Sailors' Home; Scenery on the Columbia River, 97. Reed-Birds, or Bob-a-Link, 102. New Odontograph, 105.

CORRESPONDENCE.—Personal Suffrage in Mining Companies; Geology of Prospect Mountain, 98-102. Globe District, Arizona, 102.

SCIENTIFIC PROGRESS.—On Mineral Veins; The New Star; A Possible New Metal; The Oldest Plant; The Magnet in Surgery; Levier on the Ultra-Neptunian Planets; The Liebig Monument; Electric Lightings; Neptune the Most Distant Planet, 99.

MECHANICAL PROGRESS.—Boiler Shell Drilling; Testing Tension on Iron Rods; An Atmospheric Locomotive Engine; Portable Steam Engines; Narrow-Gauge Progress; English Fear; Electric Clocks in Paris; Pension to an Inventor, 99.

MINING STOCK MARKET.—Sales at the San Francisco, Pacific and California Stock Boards; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 100.

GOOD HEALTH.—Sleeplessness; Poisonous Indian Rubber Toys; Moral Value of Physical Strength; Blue Glass for Weak Eyes; Lady Doctors in Europe, 103.

USEFUL INFORMATION.—To Take Out Glass Stoppers from Bottles; Tin-foil; Mummies Converted into Paint; Utilization of Sea-weed; Load for a Man; Artificial Beeswax, 103.

MINING SUMMARY from the counties in California, Nevada, Oregon, Colorado, Idaho and Utah, 101-8.

GENERAL NEWS ITEMS on page 108 and other pages.

MISCELLANEOUS.—Reese River Mines, 102. The Pittsburg Mine; Expensive Tunnel Developments, 103. Our Railroads; Smelting Furnaces; Miners' Water Rights; Fighting Hot War, 106.

NEW ADVERTISEMENTS.

Machinery, Parke & Lacy, S. F.; Text Books, John Wiley & Co., N. Y.; Moustache Protector, C. H. Barrows, Willamette, Conn.; Ames Portable and Stationary Engines, Baker & Hamilton, S. F.

A NEW WORK ON ASSAYING.—Prof. Pierre de Peyster Ricketts, of the School of Mines, Columbia College, New York, is the author of a new and valuable publication, entitled "Notes on Assaying and Assay Schemes," designed originally for use in the laboratories of that school, but which equally commends itself as a book of reference to the general assayer. The chief merit of the work is the system of classification of tests adopted, subjects being arranged in an especially handy manner, thus greatly facilitating practice. There is a great deal of tabulated information, and some convenient forms for reports are added. The branches of assaying most frequently required on this coast are naturally given prominence, while the methods of determining copper, iron, zinc, manganese, sulphur, etc., are also fully described. A. L. Bancroft & Co. are publishers' agents in this city.

ANALYSIS OF MINE WATER.—A sample of the water in the Hale & Norcross mine (on the Comstock), containing 54.219 grains of solid matter per gallon of 231 cubic inches, was recently analyzed, with the following results:

	Grains.
Chloride of sodium.....	1.327
Sulphate of lime.....	3.500
Sulphate of soda.....	22.582
Sulphate of potassa.....	8.342
Magnesia.....	18.518
Iron.....	Trace
	None

The iron mill in process of construction at Laramie, Wyoming, has a contract to supply 80,000 tons of rails to the Utah Northern narrow-gauge road, in addition to a large amount of work for the Union Pacific.

An Automatic Amalgam Saving Machine.

We examined, this week, at Steen's machine shop, 226 Beale street, a new device for saving gold, quicksilver and amalgam, the invention of Mr. A. I. Frick, of Oakland, Alameda county. The machine is quite simple in construction, and its operation warrants the inventor in styling it the "automatic amalgam saving machine." The principle of saving the precious metals by this device consists in having a large area of amalgamating surface in a comparatively small space, and in keeping this surface continually supplied with fresh quicksilver, so that no oxidation shall take place and the plates are always in condition to do their work properly.

To accomplish this object, a wheel with iron frame and copper buckets, similar in form to an ordinary overshot wheel, is mounted in a case about five feet long and two feet wide. Under this wheel, in the bottom of the case, is a depression corresponding to the circle of the wheel, in which is placed a quantity of quicksilver. The edges of the buckets of the wheel are turned slightly, at right angles to the buckets, so that when the wheel revolves and the buckets pass through the quicksilver, the turned-down edges will collect a small quantity and carry it up with them. As the rotation of the wheel continues, and each bucket passes the horizontal line, the quicksilver slides down the surface of the bucket. Then, as the wheel revolves, it slides over the coppered surface between each two buckets, and then over the back part of the next bucket, falling from there into the quicksilver well again. By this means all the buckets and the spaces between, at each revolution, receive a new and fresh coating of quicksilver. The edges of the buckets are turned at right angles in the direction in which they enter the quicksilver in the receptacle, and after the bucket gets at the proper position the mercury of course slides off the side easily, and the front and back of each bucket get a fresh coating. The motion of the wheel is slow and the edges of the buckets sharp, so that they slide easily through the quicksilver without cutting it up or splashing it about. A sheet of copper corresponding to the periphery of the wheel is placed in front, so that, in case any mercury should fall off the buckets, it would be run smoothly back into the receptacle without a sudden drop. A similar plate is placed behind the wheel, where the quicksilver leaves the buckets, and conducts it back to the place smoothly. All of the plates, of course, form additional amalgamating surface.

After the tailings, etc., are passed over the wheel, as described, on their way out of the machine, they pass over another depression or receptacle, for a riffle. This latter receptacle also answers the purpose of catching any particles which may have been washed over past the wheel. A revolving iron rake, which receives its motion by means of a belt attached to the shaft of the main wheel (on the outside of the box), keeps the material constantly stirred, so that the sulphurets or tailings will not cake.

The main wheel has its motion imparted to it by the water and tailings from the batteries and plates, or settlers, and consequently no extra power is required to run the machine. The arrangement is intended to be placed at the end of an ordinary row of plates, etc., or behind the settlers, in order to save any quicksilver, amalgam or gold which may pass over. It is not intended to catch sulphurets. It is automatic, as it requires no attendance whatever. A small brake with set-screws is arranged so as to regulate the speed of the wheel to conform to the flow of the water, and thus, once set, the machine will work right along without attention. Outside the box on one side is a small cup-shaped iron receptacle to draw off the surplus quicksilver which may accumulate. The cleaning up is very easily done. Each copper bucket is so arranged in a slot as to be drawn out if it is required to replace it. In ordinary cleaning up, however, the top of the box opens and plenty of space is given for the operator to clean each plate separately. The space between the buckets is wide enough to be easily reached. When the depression on the bottom is to be cleaned up the wheel may be lifted out entirely. At other times a padlock secures the whole apparatus so that it cannot be examined or touched except by the proper person. We should have stated previously that the water and tailings enter the box on the top and strike the wheel in the opposite direction to which they flow over ordinary plates, but the direction can be changed by the interposition of a sluice to lead the water to this apparatus.

Only one of these machines has thus far been made, but it seems as if there would be a good demand for them should they work as favorably as expected. The machine is very inexpensive, and as it requires no power or attention, if it only saves 50 cents a ton at a mill it would pay for itself very soon. At some places it might save a dollar or two a ton catching quicksilver and amalgam. The machine sits on four legs and requires no preparation to be set at work.

The main wheel is about three feet in diameter, and has sixteen buckets, each six inches deep and 15 inches wide. These buckets, with the amalgamating space between them and the plates in front and rear, before referred to, give an amalgamating surface of about 40 square

feet, not counting the reservoir of quicksilver described. The main feature is the fact that the whole surface receives a new coating of mercury at every revolution of the wheel, and no oxidation ensues. The machine can run night and day, and the only places to be oiled are the four journal boxes, which are outside of the main box. The machine which we examined is shortly to be taken to Virginia City, where it will be practically tried for a few months. Those interested in gold or quicksilver saving devices would do well to examine this one, which seems a very progressive step in the right direction.

Expenditures on Claims.

Keep up your annual expenditures on your mining claim, as required by law, and you will have no trouble. This is our advice to half a dozen inquirers about a construction of the United States mining law to get over this difficulty. The trouble is that the law is capable of several constructions as it stands, and, of course, those interested make the most favorable construction for themselves. Some miners have even made up their minds not to do the work required, but simply to be on hand when the year is up, and re-locate, and continue to do so. Even if this could be done, however, it would probably not conform to the local regulations, so that the claim might be jumped any day; and therefore miners pursuing these tactics stand a very good chance of losing their property.

The conditions to be complied with are simply these: "On each location prior to May 10th, 1872, ten dollars' worth of work must be performed or improvements made on each one hundred feet each year after the 1st of January, 1875. On each claim located after May 10th, 1872, not less than one hundred dollars' worth of work must be performed or improvements made each year, beginning January 1st, 1875, and thereafter until a patent has been issued therefor."

It must be borne in mind, however, that the Commissioner of the Land Office has decided that the year shall commence from the date of the location of the claim. This is not generally understood, but it is a fact.

The expenditures must, moreover, be kept up continually until a patent is issued. Failure to make the expenditures or do the full amount of work, renders the ground vacant. It will not do for the owners simply to go there on the beginning of the year and be in possession. If no one has taken the ground they must formally re-locate, record and comply with the local regulations concerning boundaries, etc., all over again, just as if it was a new claim. If this is not done the title will be faulty and one may be liable at any moment to lose his ground. A case in point has recently proven this, as the following paragraph from the Nevada Transcript will show:

"Under this law J. L. Holland and others relocated 1,500 feet of the ground known as the Mt. Auburn. The ledge had been in the continued possession of the defendants for a long time, and large expenditures had been made upon it at different times. It appears, however, that the requisite amount of work was not done on it during the year 1875—the owners doing as has been the general custom here—letting it lay idle with the hope of sometime being able to obtain means to put up machinery and work it. After a lengthy trial of the case, the jury returned a verdict for the plaintiff, and the question of hereafter holding ground in this section without a rigid compliance with the congressional enactments was thereby definitely settled. Those who now have claims on lodes, if they desire to allow them to remain idle, must obtain a Government patent, or they will wake up some morning and find themselves minus a title, and no hopes of getting one by going into the courts to do so. While we sympathize with those who are deprived of property by their ignorance of the change of the law, we yet think the general prosperity of the whole community will be increased thereby, for it establishes a rule that will result in increased activity in mining operations, and will be the means of allowing many good claims to be opened that have heretofore been idle and unproductive."

We have heard of other instances where ground in the same condition as that referred to by our cotemporary has been jumped, and under the law the re-locators will be very likely to hold their own. In some cases the mines had mills, etc., on the ground. These, of course, would not become the property of the re-locators, but the ground would.

We feel pretty certain that the law as it stands will be beneficial in the end, although it may work hardship in a few instances. If men have mines and will not work them, but wait for their neighbors to develop the camp, they ought to be made to work the claims or give a chance to some one who will. Many camps have suffered heretofore from this cause, but now the lazy ones will have to work. It will be better for the country to have these claims developed. If any one thinks he has a good claim, let him have it patented, and annual expenditure will cease. He will have a clear title, and his property will be in a condition to leave, work, or sell, as he thinks best. By all means, patent your claims as soon as you can afford to do so.

Items of Interest from the Mines.

We give below items of interest from prominent mines, most of which are collated from letters of the respective superintendents on file at the offices in this city. Considerable of this news is later than that procured from the interior journals:

The last weekly letter from the Eureka Consolidated mine says: The mine continues to improve from day to day, as work is driven forward in the various drifts, etc. The ore bodies are developing largely, and the character of the ore is such as to warrant the most flattering results for the future, and holds out the best encouragement for the permanency and lasting qualities of the mine; 10th level west drift made 19 feet, and now in 53 feet from main drift. Drift looking well, with good prospects in view. Have found some high-grade ore, which improves in quality as the drift is advanced; 9th level north cross-cut now in 118 feet. Second upraise, to case 54-foot, is completed. The ore body presents a fine appearance, and is opening out largely. The ore is of high grade and of a character easy for reduction.

Car samples of ore from the Chollar assay \$25.20 per ton.

The ore-producing stopes throughout the 400, 500, 600 and 700-foot levels of the Justice have very much improved in the general quality of the ore produced. No. 2 east cross-cut, 600-foot level, bids fair, from present indications, to make a valuable development in due course of time.

News from the Golden Chariot (Idaho) is encouraging. The 1300-foot level has attained a distance of 129 feet on vein. The character of the ore has greatly improved. A slight increase in the flow of water is noted as the drift approaches the cross-course. Sixth level winze is 31 feet in depth, with ore all the distance.

Owing to the heavy flow of water in the winze from the 1050-foot level of the Baltimore Consolidated, but little progress has been made therein. The ledge in the winze is widening and looking very encouraging.

The cross-cut east from main north drift in the Andes looks well, and indicates close proximity to a good body of ore. Assays give from \$58.30 to \$73.47. They have found a considerable deposit of ruby silver in the ore-producing stopes above the 400-foot level. The deposit is found at a height of 65 feet, close to the overhanging wall of the main fissure. The principal portion of the milling ore is produced at or near the west foot-wall of the vein.

Sinking the shaft of the Grand Prize has been resumed and no further trouble from water is anticipated.

The heat in the Hale & Norcross mine is now very great. After cleaning out 70 feet further in the drift connecting with the Savage mine, on the 1900-foot level, a winze will be reached connecting with the upper levels and securing a good ventilation.

Progress in the west drift on the 1650-foot level of the Consolidated Virginia, has been slow on account of having considerable water and hot air to contend with. The ore vein is looking well. Nothing has been done on the 1700-foot level, nor has any sinking been done in the C. & C. shaft since last report.

A Burleigh drift is to be put at work in the south cross-cut on the 1700-foot level of the Best & Belcher.

The last clean-up of the Eureka (G. V.) mine was 280 ounces of amalgam.

Some very good assays are obtained from the quartz recently encountered in the Dayton mine.

EUREKA VS. RICHMOND.—The great mining suit which has been going on in Eureka for some time past has been decided. The application of the Eureka Consolidated mining company for an injunction against the Richmond Consolidated company has been denied by Judge Cole, and the restraining order has been ordered vacated. The following is the decision: "I do not think the defendant in this case is the proper defendant. The Nevada company is not a myth. We are not here on a writ of *quo warranto* to dissolve the Richmond mining company of Nevada. The only question is that of entry and ouster. I do not think that the English company is in possession, nor that Mr. Rickard took possession in the name of the English company. All the evidence goes to show that the Nevada company are the real defendants in this suit, and in possession of the ground in dispute. The mere fact that the Richmond Consolidated mining company (limited) controls the Nevada corporation is no legal objection. I think that the testimony shows that at the time of commencing this suit, and at the present time, that company was, and is in possession of the ground in dispute. The motion for injunction is denied, and the restraining order set aside."

THE BUSINESS DIRECTORY for 1877 has just been issued by L. M. McKenney, 525 Commercial street, in this city. It is, as its name implies, a business directory of San Francisco and principal towns of California and Nevada, containing names, business and address of merchants, manufacturers and professional men in the places referred to. It is alphabetically arranged and classified under headings of business. The book is a very convenient one for everybody.

"Short Cut" Method for Describing Gear Teeth.

The rattling so common to cast gearing is due to two causes; first, the actual errors in the shape of the teeth, and second, inaccuracy of construction. The latter, being a matter of workmanship and skill alone, will not be considered here; but the former is due, to so great an extent, to want of familiarity with proper method for laying out teeth, or the tendency, when familiar, to avoid the trouble of correct delineation by guessing at the curves, that the following "short cut" plan, by means of a new *templet odontograph*, has been devised, by Professor S. W. Robinson, of the School of Mechanical Engineering of the Illinois Industrial University.

This instrument possesses the novelty of being, in itself, a ready-made and universal scribe templet, equally serviceable to the draftsman and pattern maker for laying out, with great accuracy, all kinds of gearing, and without aid from drawing instruments or elaborate books on the theory of gearing.

The instrument is founded upon theory, as elaborately demonstrated in an article which appeared in *Van Nostrand's Engineering Magazine* for July, '76; and though a considerable portion of higher analysis is required to prove its applicability, the practice is reduced to such a simple operation that the most untutored cannot fail to apply it correctly.

The full size of the instrument is shown in Fig. 1, of the engravings. It consists of a piece of flat brass about a sixteenth of an inch thick, finished and graduated on both sides alike. The two curved edges are the important elements, and each is formed from one and the same logarithmic spiral, whose "obliquity" is 2. The applicability of this curve depends upon two properties of it; first, that the involute of the logarithmic spiral is another like spiral with poles in common; and second, that the obliquity, or angle between a normal and radius vector, is constant; the latter being possessed by this curve alone. By the first property it is known that a line lying tangent to the curve *CFH* will be normal, or perpendicular to the curve *CDB*; so that when the line *DEF* is a tangent to the pitch line, the curve *ADB* will be in very close osculation with the epicycloid. By the second property all sectors of the spiral, with given angle at the pole, are similar figures, which admits of the same degree of osculation with all similar epicycloids, whether great or small, and nearly the same for epicycloids in general, thus extending the application of instrument to epicycloidal gearing in general.

These properties are found sufficient to admit of the instrument being placed, in the same manner, on an epicycloid, and in close contact with it, by aid of a number obtained from the pitch circle, the generating circle, and the number of teeth in the wheel for which the teeth are sought. These numbers, which have been styled index numbers, because they serve as an index to the scale of the odontograph, are computed with care from formulas, deduced and given in the magazine article above mentioned. The numbers, divided by the pitch, were also given tabular form in the magazine, but have since been put in much more suitable shape for practice in No. 24, of "Van Nostrand's Science Series" which contains the odontograph article, and also an article from the magazine on the forms of the teeth of wheels and from which are taken the first two cuts illustrating this description. The tables in the magazine apply for radical flanks only, but those in No. 24, "Science Series" are more complete, and extend to all gearing, such as are required for "sets" or interchangeable gears; and for teeth with flanks braced or strengthened to any desired extent.

Many of our readers will doubtless desire to learn something of the connection of this odontograph with the theory of tooth curves, without the trouble of following the line of mathematical reasoning given as above mentioned. To this end the following description of the steps is taken from the *Polytechnic Review*. But before proceeding to this, it is desirable to point out just what are the conditions of the tooth-curves the instrument is to give.

In the article on forms of teeth above mentioned, it is shown that any pair of pitch lines, circular or non-circular, may have correct working teeth described for them by taking any kind of curve whatever for a describing curve, and rolling it on the outside of one, and the inside of the other pitch line in the same direction, for generating a face and flank, which will work correctly. This operation is exhibited in Fig. 2. These tooth curves will each be wholly on one side of their respective pitch lines, one within

and the other without. The next pair of faces and flanks may be described with the same, or any other describing curve. To describe the other halves of the teeth, or the curves for the other sides of the pitch lines into which these curves are to be extended for completing the teeth, describing curves are to be similarly rolled upon the other sides of the pitch lines.

These few words really comprehend the whole general theory of gearing, which, however, is much more elaborately set forth and illustrated in the "Science Series" above mentioned. Epicycloidal gearing is therefore only a special case in which the pitch lines and describing curves are circles. Therefore, for this particular form roll any circle on the outside of one, and inside of the other pitch circles for a face and flank, and for the flank and face of same teeth, roll this, or any other circle, inside and outside respectively. We thus obtain one side entire of a tooth of each wheel, and they may be used as patterns for the rest. When the diameters of these rolling circles are equal to the radii of the pitch circles within which they roll respectively, the hypocycloids will be simply diameters of the pitch circles, and hence the tooth flanks radial. Smaller rolling circles give flaring flanks. If a given rolling circle be used for a number of different pitch circles, inside and outside, the wheels will work correctly together in any interchangeable manner, as in "sets."

Involute teeth also form a special case of the

first two gave expressions for the index numbers in terms of the diameter of the generating circle and of the radius and number of teeth of the wheel for which the teeth are sought.

For the rack and pinion the faces of the tooth of the rack are cycloidal, and the index numbers for this are given by themselves. The faces of the pinion are involutes, and hence the same table applies as for involute teeth.

The formula which give these tabular values require that the odontograph be set to a tangent, *DE*, to the pitch line *E*, being taken for the middle of a tooth. Also the index number must fall on tangent line, *DE*, the index number being 2.5 for the setting down in Fig. 1. The point of tangency, *E*, must be the middle of a tooth. The dotted circle, *A E H*, is the pitch line. When the instrument is once set, the pencil, pen or scribe is to trace the curve, *A D B*, for the face of a tooth.

The instrument has countersunk holes, shown in the cut, so that it can be mounted upon a radius rod, by wood screws, and swung around a center pin to the wheel to lay out all the teeth, in the same manner as in any other templet. The instrument can then be reversed to position for the opposite face of tooth, and treated likewise.

When the generating circle chosen has its diameter equal to the radius of the opposite pitch circle, the flanks of the teeth will be radial, and very conveniently drawn. But when

Fig. I.

NEW ODONTOGRAPH—FULL SIZE.

general theory in which the describing curves are logarithmic spirals rolled on the pitch lines. The same curves are, however, more conveniently described by unwinding a thread from a cylinder of certain size with pencil attached. The odontograph curve will represent all these curves, as far as required for the teeth of wheels, and with a wonderful degree of precision. This known, it only remains to discover a mode of

Fig. II.

setting the instrument, and of procuring the tabular values.

It is first necessary to decide on a particular logarithmic spiral, because it may have an indefinite number of obliquities. If circle arcs will give a reasonable approximation to form of tooth, as contended by some makers, then a logarithmic spiral, very carelessly chosen, even, will do far better, for it is a curve some portion of which very much resembles such initial part of an epicycloid as required for a tooth. But it is evident that some form is best, and this is found, by a method partly graphical and partly analytical, to be one whose obliquity is 2, and is the one adopted for the instrument with great confidence as to close coincidences.

An equation of the odontograph curve was next obtained, which was combined with the equations of the epicycloid, the hypocycloid, and the involute. The combinations with the

relation is otherwise, the flank will be curved, and the second part of the table is given for setting for them. The formulas, however, require that the instrument be set by aid of a different line than *DE*, for the flanks. The tangent must be drawn to the pitch line from the side of the tooth instead of middle, as from *A*, in Fig. 1. Also, the instrument should have its back toward instead of from the center of wheel. Therefore, for the flank, the end, *H*, should be wheeled around nearly 180°, and set to a tangent drawn from *A*. A similar tangent and setting is required for the opposite flank.

Fig. 3 shows at a glance how the odontograph is placed for drawing the faces and flanks.

In the case of involute teeth the settings are made in the same way as for above case of radial flanks; except the tangent, *DE*, must be drawn from the base circle of the involute instead of the pitch line. But the tooth-thickness should still be laid off on the pitch line. For all these cases the radius rod may be brought into requisition, whether the drawing is to be done on the drawing board or wooden pattern.

These instruments are manufactured at the laboratory of the School of Mechanical Engineering of the Illinois Industrial University, Champaign, Illinois.

ADVICES from Ottawa state that the Canadian government has sent to England advertisements for propositions from capitalists to build the remaining portion of the Pacific railway from the Red river to the Pacific ocean. Accompanying them is also sent a large number of copies of a book, compiled by Carroll Ryan, giving a roseate description of the soil, climate and productions of the country along the proposed line of the route.

MESSRS. BAKER & HAMILTON, as will be seen by our advertising columns, keep on hand all styles of the "Ames portable engine," such as we have described at various times in this journal. These engines have an enviable reputation for strength and simplicity of construction. They are made in different sizes and styles, to suit various kinds of works, and are furnished all ready to fire up in and run.

Mechanical Ore Concentration and Separation—No. 22.

(Written for the Press by FRANCIS M. F. CAZIN, M. E. Santa Fe, New Mexico.)

Slimes and Their Treatment.

It may contribute to more perfect information to my readers if in this place I repeat briefly what the leading features of mineral dressing are, so as to assign to the treatment of "slimes" (fine particles of less than one-half millimeter size), its proper place. After the mineral (ore) is broken into particles of such sizes as its nature will require, the material resulting from the breaking machinery (crushers, rollers, stamps or pulverizers) will practically never consist of particles of uniform sizes. The apparatus applied may control the size to such an extent as to permit no particle exceeding a specified size to collect with the broken material, but no apparatus in use or imaginable will prevent smaller sizes than those determined upon as the common result to collect with the larger sizes.

The coarser sizes—grains, coarse sand and fine sand—offer but little difficulty in classification according to size, or in separation according to quality, and it may be fairly said that the difficulty begins only with the finer sizes—those less than one-half millimeter in diameter—as well for classification as for separation. The treatment of slimes should therefore not only form an independent and special department in all concentration works, but to this department should all slimes be conducted. The slimes (dust when dry) consist of particles from one-half millimeter (1-50 inch) diameter down to particles not discernible, except under the microscope. They not only result in pulverizers or stamps, but their appearance begins in the crushers, augments in rollers and prevails in stamps and pulverizers. Even during the action of separating the coarser sizes, new quantities of slimes are the result.

It therefore is not sufficient to wash the ore before classifying so as to assort therefrom the slimes before classifying the grains and sands, but in separating grains and sands provision be made to free them from all slimes as preliminary action for their separation.

On continuous jigs with row of sieves this is done by an upper or first sieve with cloth or plate of one-half millimeter perforations, which sieve then is called the "suction sieve," because it acts as a suction-pump, drawing all slimes through and leaving grains and sands above, which grains and sands respectively form a fit object for jigs.

As stated before, all slimes, resulting from whatever part of the general operation, should be collected together and should be submitted to a special and careful treatment, because it is the nature of almost all ores that the most valuable parts break into the finest sizes, and predominantly so in ores from mines working near the surface.

In general a preliminary washing and a suction sieve will be sufficient in order to free the grains and sands from slimes, but where the ore is so soft that grains and sands, by friction during the act of separation, will produce new slimes, the then muddy water, overflowing from the jigs with the tailings, should be made to escape by itself and should pass through an apparatus called "spitz-kasten," which will be described hereafter, and which apparatus has the designation not to separate, but only to collect the slimes out of the muddy water. The water from the jigs can be made to carry all slimes contained therein away from the grain or sand tailings, if the latter are elevated out of the water, either by a perforated "Raff wheel," or by an inclined Archimedeian screw, as the late Ritter Von Rittinger, the great authority on mineral dressing in Europe, suggested in a letter to the author, and as was successfully applied afterwards.

In elevating the grains and sands, a supplementary stream of fresh water during the act of elevation secures a complete recovering of all slimes.

BULLION SHIPMENTS.—Since our last report shipments from the prominent mines have been as follows: Northern Belle, Feb. 4th, \$18,005.99; Con. Virginia, 8th, \$64,763.37; California, 8th, \$300,639.89—total for January, \$1,613,707.39; Comanche, Feb. 6th, \$9,640.85; Northern Belle, 6th, \$12,015.83; Manhattan, 13th, \$12,200; Leopard, 12th, \$6,800; Con. Virginia, 13th, \$59,090.52—total to date, \$122,853.89; California, 13th, \$266,612.19; Tybo Con., 8th, \$8,508.04; Northern Belle, 11th, \$18,008.93.

Our Railroads.

Railroad Construction in 1876.

The last number of the *Railroad Gazette* contains a full review of the railroad construction of 1876. It appears from the exhibit that, though the construction of new roads has been small as compared with those years in which building was most extensively carried on, the progress was material and healthy. The time has gone by when railroads could be built on speculation and prove profitable enterprises for those who first took the project in hand, and whatever the effect might be upon those who had to bear the brunt of the undertaking.

Texas, California and Colorado exhibited the most marked railroad progress in 1876. The first named State built nearly as much railroad during the year as it ever did in any preceding year, and increased its mileage more than one-fifth. Both California and Colorado constructed more railroad than in any previous year. Ohio led Colorado in the number of miles, but not in the proportion of mileage to the existing length of road.

There are three States which have over 5,000 miles of road; six States which have over 3,000 and less than 5,000; 16 States with more than 1,000 and less than 3,000 miles; 18 States and Territories with over 100 miles of road and less than 1,000; and five Territories in which not a single mile has been constructed.

The following summary shows the mileage of new railroad constructed in each State and Territory for the year 1876, and the total mileage at the end of 1876:

	Construction in 1876.	Total Mileage.

Smelting Furnaces.

In a recent number of the *Coso Mining News* there was an article relative to smelting, in which the Eureka smelters were advised to take a trip to Coso in order to learn their business. In answer the Eureka *Sentinel* called for a few facts relative to the capacity of the Coso furnaces, their bullion production, cost of running, etc. The next issue of the *News* supplied that information, and, says the *Sentinel*, we have taken pains to gather some statistics in relation to our own furnaces. The following is a tabulated statement of the working expenses and amount produced over in Coso:

NEW COSO EXPENSES FOR ONE DAY.	
One Foreman.....	\$ 10 00
Two Assistant Foremen.....	10 00
Two Engineers.....	10 00
One Machinist.....	6 00
One Blacksmith.....	5 50
One Helper.....	4 50
One Carpenter.....	5 50
Three Changers.....	15 00
Three Smelters.....	15 00
Three Helpers.....	12 00
Two Coal-passers.....	9 00
Five Laborers (ore men).....	20 00
One Cartman, horse and cart.....	6 50
One Night Watchman.....	5 00
Iron ore, 6 tons per day used at \$16.50 per ton.....	99 00
Lime rock, 14 tons per day used.....	50 00
Charcoal per day.....	395 00
Wood, 6 cords per day.....	60 00
Water, per day, 3,000 gallons.....	30 00
Sundries, oil, etc.....	00 00
Total expenses per day.....	\$780 00
Total expenses for 17 days.....	\$13,260 00

The furnace is of 50 tons capacity, and when running well, smelts an average of 20 tons of ore per day.

DEFIANCE EXPENSES FOR 17 DAYS' RUN.	
Coal, 14,800 bushels, at 32 cents.....	\$4,736 00
Labor.....	1,564 00
Wood, 34 cords, at \$11.....	374 00
Iron ore, 30 tons, at \$16.50.....	495 00
Water, at \$22 per day.....	374 00
Sundries, at \$5 per day.....	85 00
Total.....	\$7,628 00

The furnace is of 30 tons capacity, and has smelted in the 17 days' run 550 tons of ore, at an average cost per ton of \$12.05.

By these figures, which are very nearly correct, it will be seen that the Defiance has smelted its ores at an average expense of \$12.05

per ton, whereas, the New Coso Co. has smelted its ores at a cost of \$39 per ton.

The following is the daily workings of a Eureka furnace—the number of men employed, cost, etc.:

EUREKA EXPENSES FOR ONE DAY.	
Two Foremen.....	\$ 12 00
Three Smelters.....	15 00
Six Slag-wheelers.....	24 00
Six Ore-feeders.....	24 00
Four Ore-wheelers.....	16 00
Two Charcoal-tenders.....	8 00
Two Engineers.....	10 00
One Cartman.....	4 00
Charcoal, 1,650 bushels.....	495 00
Wood, two cords per day.....	12 00
Sundries, oil, etc.....	10 00
Total.....	\$630 00

The furnace was built in 1872, has been running a greater portion of the time up to the present date, and was calculated for a capacity of 50 tons, but has averaged 70 tons of ore reduced daily, and run as high as 90. The average cost of reduction is \$9 per ton, and bullion produced will reach from eight to nine tons per day. With the figures given by the *News*, we fail to see how, on the most favorable showing, he gets the cost per ton at \$12.05; but granting such to be the case, it will be seen that our furnaces double the production and reduce the cost one-quarter. Better have those Coso smelters do a little "barring out," or else take a trip over to Eureka and learn the business.

Miners' Water Rights.

The case of Osgood versus the E. D. W. and D. G. M. Co., which has just been tried in the District Court, excited much interest and involved several points of great and general importance. Both sides were represented by able counsel: Messrs. McFarland, of Sacramento, and Virgin, of Nevada, for plaintiff; Creed Haymond, Judge Garber and George G. Blanchard for defendant. The case went to the jury, and after brief deliberation they returned a verdict for defendant. As a complete and felicitous summary of the points of the case, we append Judge Wheeler's verbal charge to the jury, as transcribed from the short-hand notes of S. Osburne, stenographic reporter, and published in the *Mountain Democrat*, El Dorado county:

Gentlemen of the jury: It appears in evidence in this case that the plaintiff settled and located upon his quarter section of land in Lake valley, El Dorado county, as early as 1863; that he made an application to the proper land office and entered the land through which the stream runs; that on the 11th day of June, 1870, he proved up his claim and paid the purchase price to the United States Government. On making that payment he became the equitable owner of the land, and all that remained then to be done was the mere ministerial act, upon the part of the subordinate officers of the Government, of making out and delivering to him a patent. But for the purposes of this case he will be deemed to have become the owner of the land upon that day—the 11th day of June, 1870.

I instruct you as matter of law, and such I consider clearly the weight of the authorities in the United States as well as England, that the owner of a piece of land through which a stream of water runs is entitled to have that stream continue to run in its natural course, with its flow undiminished and its volume of water unpolluted. That is unquestionably what is called the "riparian doctrine of the common law;" and while I have listened with great attention, and I might say with instruction, to the argument of counsel for defendant upon that point, undertaking to establish that that law has been changed, I must instruct you that the weight of authorities is the other way; that the law stands to-day in California, concerning riparian rights, precisely as it stood one hundred years ago in England, and as it exists in most if not all of the States of the Union. If, then, this defendant, this corporation, had had no existence, or had never taken any steps to claim the waters of this creek, the plaintiff in this case, by virtue of his purchase of the land from the U. S. Government, would be entitled to the unobstructed flow through his land of the whole stream. Having shown this payment to the Government, he has established a *prima facie* case, and shown that he is entitled to the relief he here demands. But I will remark here that it is not necessary, in order to maintain his action, that he should go into proof of the particular use to which he proposes to apply this water. That with him is a matter of taste; a matter of choice; a matter of right; and as well might a stranger question the owner of a shade-tree growing upon the lawn as to what use he proposed to put it to, as for the defendant to question the plaintiff as to the special use he proposes to make of this stream.

In answer to the plaintiff's showing, the defendant sets up, as a reason why the plaintiff should not prevail, that the corporation defendant has acquired rights from and through the General Government which have become, by virtue of the acts that it, the defendant and its grantors, have performed, paramount to the rights of the plaintiff. It is in evidence and beyond dispute that in 1867 the grantors of the corporation posted at the outlet of Echo lake a notice claiming the waters of that stream for certain purposes. It is also claimed by them that subsequent to the posting of that notice, and down to the time in which they actually turned the water into their flumes, they acted with reasonable and proper diligence; that they surveyed their lines for the flume and ditch; that they worked upon the ditch below Cedar rock, and that in all things they followed up the

object that the notice announced to the world, with diligence and with good faith, with as much rapidity as it was practical to do under the circumstances of the case, locality and climate, and the condition of the country considered.

It is admitted in this case that down to 1867 the U. S. Government was the owner, not only of the land upon which Osgood settled but also of the land at and immediately surrounding Echo lake, and being thus the owner, being the paramount proprietor, it was perfectly competent for the American Government, in the exercise of its constitutional rights and of its discretion, to make such disposition of the land or the water as it saw fit. In the year 1866, in the exercise of that discretion, and with a view to the peculiar condition of things upon this coast, it passed an act the 9th section of which it is claimed by defendant conferred rights which they are now seeking to enforce in this case. That section reads as follows: "That whenever by priority of possession, right to use of water for mining, agriculture, manufacturing or other purposes, have vested and accrued and the same are recognized and acknowledged by the local customs, laws and the decisions of courts, the possessors and owners of such vested rights shall be maintained and protected in the same, and the right of way for the construction of ditches and canals for the purpose aforesaid is hereby acknowledged and confirmed."

The first question that is made upon this section is whether priority of possession meant an actual possession, an actual diversion of the water of the stream, or whether it meant the taking of such initiatory steps as under the decisions of our courts here constitute what the court calls possession of a water right, and before the flumes, ditches, reservoirs and dams are finally completed.

In the review that I have taken of the decision of our Supreme Court defining what is possession, I am constrained to believe, and therefore charge you, that if the parties had posted the proper notice, had blazed trees, had made their surveys and had done the necessary and usual amount of work evincing their good faith, and had been diligent in the prosecution of the work as far as it was in their power to be under all the circumstances of the case, I charge you that that, in the sense of the law, constitutes possession, and if their work was afterwards pursued with due diligence on to completion, that their right related back to the date on which they posted their notice, which would be in 1867.

I also instruct you that this act of Congress was intended to operate upon future acquisitions of water rights, as also that it was not confined strictly to the mineral belt. The argument made by counsel is apparently a forcible one, that this statute was dealing with all the mineral lands on the Pacific coast, and therefore it could not have any application outside of what is called the mineral belt. To that the reply is, that Congress must have taken notice of the fact that the streams running through the mineral belt of this slope have their rise high up in the mountains, and beyond the actual mineral belt, and therefore it must have been contemplated by Congress that while the water would probably be used mostly for mining, yet that parties could go above and beyond the mineral belt and make their locations and appropriate the waters that were gathered in those high mountain lakes as natural reservoirs. You will observe then, this being the law, and it is your duty as sworn jurors to accept the law from the court as the law of the case, whether it be right or wrong—you will observe that this case then turns upon the question of the diligence of the locators, who are the grantors of defendant.

Now, it certainly would be a great injustice, and one that the law denounces, that any man would have the right to monopolize the waters of a vast extent of country by putting notices at different lakes, or at different points on rivers and streams, and then to subside into idleness and inactivity waiting merely for an opportunity to make a speculation by effecting the sale of the water thus claimed. Hence he must follow up the notice by a diligent endeavor to utilize the waters and turn them from the stream and to apply them to some useful and beneficial purpose. Again, the question has been raised, whether a man can offer as a plea for his dilatory conduct the fact that he was poor. The instruction that was read from one of the cases seems to have received the approval of our Supreme Court, that want of pecuniary ability is not an excuse for a neglect to diligently prosecute the work; that if a man has no means he cannot appropriate a large amount of water and lie idly by, waiting for an opportunity to sell it and neglecting to perform the necessary work to effect an actual diversion. If a man were permitted to do that, he could keep large and valuable industries lying idle, and might prevent men who had means, and who had the energy and the will, from going on and diverting and utilizing large and useful streams. Therefore, that plea of itself, that these gentlemen had not capital, will not and does not constitute a legal excuse for neglecting to prosecute the work, if you should find that they have been negligent in the matter.

There is one other point upon which I have been asked to instruct you; that is, that work done with a view solely to appropriate the waters of Silver lake or Clear lake will not inure or aid in effecting an appropriation of the waters of Echo lake. In looking at the diagram that was furnished by the engineer of the

defendant, it seems that Silver lake and Clear lake lie far to the south of Echo lake; that the streams flowing from those two lakes unite and form Alpine creek, which empties into the American river at or near Cedar rock, and that one of the branches of the American river, distinct from Alpine creek, and some distance from it, is the one that approaches nearest to the waters of Echo lake. I therefore instruct you that any work done between Cedar rock and Silver lake or Clear lake, with a view to appropriating the waters of those lakes, would not inure to the enterprise so far as to count in favor of the projectors in taking the waters of Echo lake; but if you are satisfied that the main ditch running from Cedar rock to Sportsman's hall was constructed with the view not only to take the waters of Clear lake and Silver lake, but also of Echo lake, then any work done upon the main trunk of the ditch, anywhere between Cedar rock and Sportsman's hall would be work tending to a final consummation of the plan of appropriating the waters of Echo lake, and it would not be necessary to do the work immediately at the lake itself. But you will remember further, that in claiming credit for work done at a remote point, to make the appropriation of Echo lake good, you must be satisfied that they gave a proper and reasonable publicity to the claim that they were making, by notice and other indications upon the ground, so that a man in the exercise of his ordinary faculties might have readily discovered that the waters had been so claimed, and that the claimants intended on the completion of the work to appropriate them.

I will say further that this question of diligence of the law seems to have reposed in the hands of the jury; it seems to have been left to you to say, as sensible business men, acting without prejudice and without fear or favor, under your oaths, whether, all the circumstances considered, there has been ordinary and proper diligence used by the locators. This depends generally upon the evidence, upon the shape of the country, upon the condition of the mountains, upon the character of the climate and upon the circumstances that might naturally arise in the course of the prosecution of the work. You are the judges, the sole judges, as the law says, of the facts. You are the judges of the credibility and the truthfulness of witnesses, and where there is any conflict it is for you to determine upon which side lies the truth. There has been something said in argument touching the fact that an individual is upon one side and a corporation upon the other. I will simply say that it is the pride and glory of our Anglo-Saxon civilization that perfect and exact justice is meted out, not only to combinations of men—corporations—but to individuals standing singly and alone in our courts of justice. You will, therefore, have no prejudice against this corporation because it is a corporation, nor should you stand in any fear of it by reason of its wealth and power, and upon the other hand you should not allow any undue sympathy for the individual to swerve you from the exact line of duty, nor should you forget the rights of the individual on account of the plea that the public would be benefited by his property being taken. The humblest individual has a right to the full protection of the law and to a fair and full recognition in our courts of all his rights.

If at any period after the posting of the notice at Echo lake the work of the defendant or its grantor was not prosecuted with due diligence, yet if, before the plaintiff's right intervened, the prosecution of the defendant or its grantor's work had been recommenced, and after such recommencement carried on with due diligence, the plaintiff cannot take advantage of the prior neglect of the defendant or its grantors.

Believing, gentlemen, that with these remarks, the testimony being fresh in your minds, as well as the very able argument of counsel, you are prepared to render an intelligent verdict, the case is submitted for your consideration. If you shall find for the defendant, your verdict will simply be, "for the defendant." If you find for the plaintiff, the verdict will be, "for the plaintiff," or with such damages as you may find that he has sustained. I apprehend, however, under the evidence, that the damage could not be anything more than nominal, which is generally fixed at \$1.

Fighting Hot Water.

The struggle with the water in the Savage and Hale & Norcross still goes on. On the 28th ultimo, and when the broken rod at the Savage was repaired, the water had risen 24 feet above the 1900-foot level in the Hale & Norcross. One set of pumps, although 14 plungers of 8 feet stroke, cannot well hold the water that flows into these mines. It requires about 12 strokes per minute of these monstrous pumps to do this. The engines are more than capable of that motion, and were the shaft perpendicular might hold the water; but the rods on the incline running at that rate would hardly stand the pressure; they would be apt to jump the rollers; but when both pumps are at work, they lower the water over six inches an hour.

Tuesday morning the 1900-foot level was again freed, and work then commenced in both mines. It took, however, until this morning to clean up, repair and reach the faces of the drifts. The lagging is always found more or less broken after a mine has been inundated, and a great deal of clayey slime is deposited by the water.

Sansome St.

Continued from page 101.

in fact, it is the only mine in Idaho Territory that has been constantly running that has been a success. This has been done by economy and good management. Gold predominates in the Gold Hill mine, with traces of silver as they get depth. Their gold assays average as high as \$17.50 per ounce. The future of the mine is very promising, as they are able to mill and mine their ore for \$2.50 per ton.

Oregon.

GOOD CLEAN-UP.—*Badrock Democrat*, Feb. 7. A company of miners, consisting of Messrs. Jack Chapman, Wm. Reynolds, Captain Jinks and Joseph Daws, who have been getting out rock on their own responsibility at the Virtue mine for a month or two past, made a handsome clean-up last Saturday. The amount derived was about \$1,800. Messrs. Borman and Co. commenced crushing rock last Saturday, at the same time, and we are promised the result of their clean-up as soon as it is ascertained. The men comprising both companies are hard workers and deserve success.

SOLD.—The Monumental mine, at Granite creek, has been sold to some San Francisco capitalists for \$50,000. Twenty thousand dollars was paid down, and the balance will be paid in six and twelve months. This is a bona fide sale and no humbug. One of the conditions of the sale was that the mine should be erected on the mine immediately, which will improve the value of mines in that vicinity 10%.

Utah.

DRY CANYON MINES.—*Cor. Salt Lake Tribune*, Feb. 6: At present there is considerable excitement here owing to the recent rich strikes in several of our mines. The Hidden Treasure mine still continues to yield large quantities of the rich ore of which you made mention in your columns a few days since. This mine is working a force of 20 men. The Mono mine has recently made a shipment of 15 tons of ore that will average about \$150 to the ton. It is rumored around town that there was a large body of high grade ore struck in this mine last week on the 600-ft level. The Queen of the Hills still keeps the ore teams busy hauling away large quantities of ore to the Chicago smelter. This mine employs between 40 and 50 men. The Deseret mine has made a rich strike, and has been shipping large quantities of ore that will average \$400 to the ton. This mine is working about 20 men. The Utah Queen is shipping considerable low grade ore. The Sky-Gazer lode is showing a three-foot vein of free milling ore, averaging 25 ounces silver to the ton. The Hidden Treasure mine still continues to ship from 20 to 30 tons of ore per day. Their new tramway is nearing completion. This will carry the ore down to Porcupine gap, from which place it will be conveyed down the canyon by ore teams, doing away with the Gibborn toll-road. At present it employs in the neighborhood of 125 men. The Chicago mine continues to take out and ship ore right along, employing 10 men. The Fourth of July has been leased by Wm. Davis and P. J. Sullivan for three months. These parties have made a rich strike, showing a vein of ore three feet wide, which will sample 40 ounces silver to the ton and 50% lead. The Rattler mine is working 10 men. They are taking out ore and the prospects look favorable. There are several other prospects in this camp which it is impossible for me to name and give a description of at this time. At all events, there are plenty of mines here, if properly developed, that would rank with the Kearns, Mono, Queen, Treasure and other noted mines. All that the camp needs to help it out is men with capital, and that is what we expect to have here this coming summer.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's office at San Francisco.

IDA LIVINGSTON & G. M. Co.—February 12th. Location, El Dorado Co. Capital stock, \$60,000. Directors—F. P. Latson, and M. Rosekrans, E. A. Sawyer, M. H. Colley and A. Y. Fanner.

CAMDEN M. & Co.—February 14th. Location, California. Capital stock, \$400,000. Directors—E. B. Pond, J. H. Suydam, Joseph Evans, John McAllister and W. B. Maddox.

LUCKY JACK M. Co.—February 14th. Location, Mono Co. Capital stock, \$5,000,000. Directors—Wm. M. Lent, J. Miller, Chas. W. Tozer, Geo. S. Dodge and A. W. Rose, Jr.

MONROE M. & M. Co.—February 14th. Location, Yuba Co. Capital stock, \$5,000,000. Directors—H. P. Mosher, John Springer, W. Applegarth, J. T. Vineyard and L. W. Gitchell.

ESSER M. Co.—February 14th. Location, Arizona. Capital stock, \$10,000,000. Trustees—A. W. Blair, W. H. Boothe, W. H. Stanley, G. W. Hopkins and D. J. Edgars.

THE EMMA MINE.—Counsel for defence in the Emma mine suit made a motion in the United States Court of New York to dismiss the complaint, or for the Court to instruct the jury to find a verdict for the defendants on the ground that plaintiffs had produced no evidence to show any false representations in connection with the sale of the mine in England, or to impeach the truth of the statements of Professor Silliman regarding the richness of the mine. Judge Wallace, in the United States Court at New York, denied the motion to dismiss the complaint, on the grounds that plaintiffs had not produced evidence to sustain their case. Counsel for the defence continued his opening, sketching the history of the mine and manner in which the defendants became the owners of it. He said they would show that the mine was all that it had been represented to be; that \$3,000,000 worth of ore had been taken out of it since it was claimed that the mine was worked out; that the mine was closed and represented to be worked out so as to make a basis for this suit, and that there were millions of dollars in it yet.

PRACTICAL WORKS.—John Wiley & Sons advertise in another column, text books and practical works for schools, institutes, engineers, architects, etc. We have called at their store and are well impressed with the apparent first-class manner in which they are conducting their specialty. We are pleased to call attention to their advertisement and invite our readers to open correspondence with them for any works in their line, of which only a few are enumerated.

BEST BOOK FOR EVERYBODY.—The new illustrated edition of Webster's Dictionary, containing 3,000 engravings, is the best book for everybody that the press has produced in the present century, and should be regarded as indispensable to the well-regulated home, reading-room, library and place of business.—*Golden Era*.

The cost of the new building of the San Francisco Stock and Exchange Board will be \$400,000.

PATENTS AND INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

(FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.)

FOR WEEK ENDING FEBRUARY 6TH, 1877.

ROCK DRILLING EXCHANGES.—Prescott S. Buckminster, S. F. **HENKERS FOR SEWING MACHINES.**—Charles L. Goethals, Los Angeles, Cal.

OVERSEAMING SEWING MACHINES.—John S. Hall, Monterey, Cal.

HARROWS.—Charles Keehner, Roseville, Cal. **GOPHER GANO PLOWS.**—Morgan S. McMahon, San Jose, Cal.

GALVANIC SOLES.—Erastus H. Craw, Vallejo, Cal. **CARPENTER'S GAGE.**—Charles O. Farciot, S. F.

CHURNS.—Elias Groat, Napa, Cal. **SOFA BEDSTEPS.**—August Hansen, S. F.

BARREL TAPS.—Henry Saunders, S. F. **AUTOMATIC SEWER TRAPS.**—John P. Schmitz, S. F.

PLUMBERS' TRAPS.—Louis Schonberg, S. F. **TELEGRAPH INSULATORS.**—Paul Sells, S. F.

SLAG POTS.—Henry Zottman, Eureka, Nev. The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of mention:

IMPROVEMENT IN CHURNS.—Elias Groat, Napa. This invention relates to certain improvements on a churn, for which several patents have been granted to the same inventor. The churn described in these other patents consisted essentially of a box, case or vessel having two parallel horizontal shafts extending longitudinally across it near its top. Each of these shafts is provided with two or more depending beaters, which were so arranged that the beaters of one shaft alternated with those of the other. A rocking motion was then imparted to the two shafts, so as to cause the beaters to be reciprocated alternately past each other inside of the box, case or other vessel, thus producing the necessary agitation. Experience has demonstrated that the device for communicating this alternate rocking motion to the horizontal shafts must not be connected with the framework or case of the churn, as the working strain which results from the short up and down strokes of the operating lever is too severe on the points of the framework. The inventor has therefore devised a cheap and simple mechanism for operating these shafts directly from their projecting ends, so that the strain will not be communicated to the case or framework. He has also invented an improved manner of constructing the end of the box from which the journals or shafts project, the object of which improvement is to allow the shafts and beaters to be easily removed when it is desired to clean the box.

SOFA AND BED.—August Hansen, S. F. This patent covers an invention which relates to a novel construction of that class of household furniture known as sofa-beds, and it consists in the formation of a double sofa bottom so hinged as to open outward to secure a proper width for a bed, and in combination with this, a sofa back so hinged as to swing across the head of the converted bed where it is inclined, and held in position by a locking device. A mid-leg may support the front of the bed, and the upholstered arms of the sofa are hinged so as to be turned back before opening out the hinged bottoms, thus protecting them from wear upon the floor or carpet. In combination with this sofa is employed a double detachable head-piece, composed of two parts, which, when not in use, may be shut up together, but are separable for use. The hinges by which the parts of the bed are connected, are so made as to brace and resist the separation of the parts.

ELECTRO-MAGNETIC SOLES.—E. H. Craw, Vallejo. This is a novel sole for boots and shoes, which is intended to create a feeble magneto-electric current through the lower limbs of the wearer, thereby relieving or curing rheumatic attacks. These soles are made of a positive and the other of a negative metal, suitably covered to prevent wear and breakage, the covering being also perforated if desired. For neatness and convenience the soles are covered with any suitable fabric. The plates are made preferably in three parts, and are loosely connected together by the covering fabric, so that as the foot and shoe bends at the ball in the movement of walking, the plates will give easily without breaking. The effect of these plates, the inventor says, has been to completely cure rheumatic affections of the lower limbs in all cases where the soles have been worn; and they require no special attention or adjustment from the wearer.

BARREL TAP.—Henry Saunders, S. F. This invention relates to certain improvements in that class of barrel taps which are fixed in the barrel and provided with a valve which is opened upon the introduction of the faucet so that by use of the faucet the contained liquid may be drawn at will. The invention consists in the employment of a double tap consisting of an outer gland, which is screwed permanently into the cask; and an inner one, which contains

the valve and receives the faucet, said inner gland being removable from the outer one so as to allow free access to the cask for cleaning, without interfering with the valve or removing the gland which screws into the cask, which would in a short time cause it to leak. It also consists in a novel construction and arrangement of the valve.

PLUMBERS' TRAP.—Louis Schonberg, S. F. This is an improvement in waste-pipe traps for plumbers' use, and it consists in enlarging the pipe on one side of the "S" bend and reducing it on the opposite side. The object of this construction is, first, to prevent siphoning, and secondly, to avoid the formation of shoulders or projections on the inside of the pipe. This is another step in advance toward preventing the access of sewer gas into dwellings, and we shall shortly give an engraving of the device, so that it will be better understood than by a mere verbal description.

An Important Decision to Miners.

Judge Sawyer, of the United States Circuit Court, in this city, has rendered a decision in the case of Trafton vs. Nougues, which will be of interest to all mining litigants. This action was brought in the State Court, in Placer county, to recover the trespass upon a gravel gold mining claim, and seeking an injunction restraining the working of the claim by the defendant, and decision was given upon a petition to have it transferred to the United States Circuit Court. Judge Sawyer, having stated that he had found considerable difficulty in construing the Congressional act of March 3d, 1875, defining the rights of citizens who lay claim to public property, gave an elaborate review of the questions involved in the case. After a lengthy introduction he said: With reference to mining claims, the act of Congress grants certain rights to those who discover, take up and work mining claims. But it refers the parties to the local laws of the States and Territories, and to the regulations of miners of the district where the claims are situated, for the measure of their rights. If a dispute arises, the act of Congress refers the parties to the ordinary tribunals to determine it by the local laws and customs, and not by the act of Congress. Clearly, the great mass of these cases cannot involve the discussion of any dispute as to the construction of any act of Congress; and when they do not, under the decisions cited, this Court is without jurisdiction, so far as this provision of the act is concerned. No controversy can possibly arise under the Constitution or an act of Congress, when all parties agree as to its construction. There may be a contest as to other matters, but not as to the Constitution or laws in such cases. Under the fifth section of the act, it is made the imperative duty of the Court, at any stage of the proceedings, when it appears that "such suit does not really and substantially involve a dispute or controversy properly within its jurisdiction," to stop the proceeding and remand the case. The location of the mine involved in the case is more than 150 miles from San Francisco, where the court is held, and many other cases may arise in this State, Nevada and Oregon, in regard to claims lying from 300 to 500 miles distant from the places where the national courts are held, and between which places the means of communication are by no means easy or cheap. Generally, in this class of cases, the testimony rests mainly in parol, and there is a multitude of witnesses. The expense of prosecuting or defending such suits, at a large distance from the location of the mines, would be enormous. If the Court should accept a petition containing a bare statement of the opinion of the petitioner that the rights of the parties are derived under an act of Congress, as in this case, the result in most cases would be that the Court would not be able to determine whether the case "really and substantially involves a dispute or controversy properly within the jurisdiction of the court," until the close of the testimony, when it would be necessary to remand the case at last. Such results would largely obstruct the administration of justice, and work an inconvenience to honest suitors. Besides, it would encourage transfers of cases over which the court had no jurisdiction, by unscrupulous parties, for the very purpose of deterring the adverse party from pursuing his rights by reason of the delays, inconvenience and enormous expense of prosecuting an action of this class at a great distance from home. These difficulties would be especially onerous in cases relating to mining rights, where time is often as important as the right, in the several large States of the Pacific coast and interior of the continent, and where a court is held at but one point.

In view of these, in my judgment, weighty considerations, therefore, I think it of the highest importance to the rights of honest litigants, and to the due and speedy administration of justice, that a petition for transfer should state the exact facts, and distinctly point out what the question is, and how and where it will arise, which gives jurisdiction to the court, so that the court can determine for itself from the facts, whether the suit does really and substantially involve a dispute or controversy properly within its jurisdiction.

The Court ordered that the ease be returned to the State Court from whence it came, with costs against the petitioner, but said that as it was of the utmost importance that a final decision of the question be had as soon as possible, he would, if counsel so desired, order the Clerk to delay returning the case till they have an opportunity to sue out and perfect a writ of error.

General News Items.

The Panama Star and Herald says guerrilla skirmishes and wholesale assassinations continue in the interior.

The Treasury Department at Washington has prohibited the importation of cattle and hides from Germany until further orders, in consequence of the rinderpest.

The general freight agents have fixed temporary rates on freights through from Chicago to Liverpool, which are an advance of five cents over those heretofore prevalent. They are on the basis of 52 cents for wheat per 100 lbs. and 53 for corn.

EARL RUSSELL has given notice to the House of Lords that he will move that England shall cease all diplomatic intercourse with Turkey, on the ground that that nation is still barbarous and unworthy of rank among the enlightened people of Europe.

The Times dispatch from Calcutta says: In the week ending February 2d, the number of persons engaged in relief works decreased 34,000 in Bombay and 39,300 in Madras, as compared with the numbers employed in previous weeks. This decrease is attributed to a reduction of wages and the exclusion of persons not really destitute. But there has been no rain and no improvement in the condition of the crops. The health of the population in both presidencies is bad. There are many cases of cholera in the distressed districts of Madras.

GRAND CENTRAL HOTEL, N. Y.—This hotel, in accord with its title, is most desirably situated for business men and pleasure seekers in the great metropolis of the United States. Like the Palace hotel west of the Rockies, it is the largest house east of the Alleghenies. It is conveniently arranged, and rendered very comfortable in each department by the successful management of the proprietor, Mr. H. L. Powers, and his associates. The interests of guests, for safety and security, are especially provided for. Its prices (from \$2.50 to \$4.00 per day, according to location of rooms and suites) are popular in these times, and we find it the liveliest house of so high a class in New York.

WOODWARD'S GARDENS embraces an Aquarium, Museum, Art Gallery, Conservatories, Tropical Houses, Menagerie, Seal Ponds and Skating Rink.

SCIENTIFIC PRESS

Patent Agency.

Publishers, Patent Agents and Engravers
224 SANSOME STREET, SAN FRANCISCO.

Mining and Scientific Press.

Is the leading mining journal in America, and enjoys a large circulation among the more intelligent operators and workers in the gold fields of the world.

As a scientific and mechanical representative of the Pacific Coast, it is decidedly popular and a standard journal with the most thrifty industrial people of the Pacific States and Territories. Its authority is of the highest order, and its usefulness in its special sphere unrivalled.

Every public library, mining engineer, metallurgist, mining operator and intelligent mechanic and manufacturer will find profit by its reading.

Subscription, \$4 a year in advance. Sample copies, post paid, 10 cents. As an

ADVERTISING

Medium for the Pacific Coast, it is superior to any other journal for all kinds of mining and hydraulic machinery and other mechanical work, building materials, new manufactures and inventions. Our rates are very reasonable compared with those of other first-class journals.

DEWEY & CO., Publishers.

MINING AND SCIENTIFIC PRESS.—This is the best journal of its class in the United States. It is published in San Francisco, by Dewey & Co., at \$4 a year, and is now in its 34th volume. Nothing that can be of interest to miners escapes its notice. Its contents are varied, and of great interest to all readers who are curious in regard to general science or specific detail. The proprietors have just given it a new dress of clear, sharp-cut type, which gives it a very handsome appearance. It is an exchange we value highly. —Colorado Miner.

WOODLAND, CAL., Aug. 8th, 1876.

Messrs. Dewey & Co.—Gents: Your letter containing the patent for my Centennial churn has come duly to hand, and you will please accept my many thanks for the prompt manner in which you attended to the business entrusted to your care, and I will take great pleasure in recommending you to any one having anything to attend to in your line. I am having a number of the churns put up, which will be ready for sale in a few weeks.

Yours truly, JAMES ROOT.

THE MINING AND SCIENTIFIC PRESS is the leading journal in America. New processes and mechanical inventions are illustrated and discussed in its weekly issues. It is a 16-page sheet, handsomely printed, for \$4 per year. Dewey & Co., publishers, San Francisco.—Mt. Lincoln News, Alma, Colorado.

Scientific and Practical Books
on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS OFFICE, S. F.

BY GUIDO KUSTEL,
MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their respective Metals without Quick-silver. 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore. It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. Price, \$2.50 coin, or \$3 currency, postage free.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. PRICE, \$7.50.

Designing

CALIFORNIA THEATRE, Bush Street, above Kearny. Open every evening with the best Dramatic Company in the United States. Box office open from 9 A. M. to 10 P. M. Seats may be secured six days in advance. Doors open at half past seven.

Mining and Other Companies.

Dolores Consolidated Mining Company.
Location of principal place of business, San Francisco, Cal. Location of works, Dolores Mining District, Esmeralda County, Nevada.

Notice is hereby given, that at a meeting of the Board of Directors, held on the first day of February, A. D. 1877, an assessment, No. 1, of 10 cents per share, was levied upon the capital stock of the corporation, payable immediately, in United States gold coin, to the Secretary, at the office of the company, 418 California street, San Francisco, Cal. Any stock upon which this assessment shall remain unpaid on the 14th day of March, A. D. 1877, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Wednesday, the 11th day of April, A. D. 1877, to pay the delinquent assessment, together with cost of advertising and expenses of sale. By order of the Board of Directors.

J. W. CLARK, Secretary.

Office, Room No. 2, 418 California street, San Francisco, California.

Mariposa Land and Mining Company of California—Location of principal place of business, San Francisco, California. Location of works, Mariposa County, Cal.

Notice is hereby given, that at a meeting of the Board of Directors, held on the sixteenth day of January, 1877, an assessment (No. 9), of one dollar per share was levied upon the capital stock of the corporation, payable immediately in United States currency, to the Secretary, at the office of the company, Room 33, Nevada Block, No. 309 Montgomery Street, San Francisco, California, or to the Assistant Secretary, at the office, No. 9 Nassau Street, New York, N. Y. Any stock upon which this assessment shall remain unpaid on the seventeenth day of February, 1877, will be delinquent, and advertised for sale at public auction; and unless payment is made before will be sold on Monday, the nineteenth day of March, 1877, to pay delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

LEANDER LEAVITT, Secretary.

Office, Room 33, Nevada Block, No. 309 Montgomery Street, San Francisco, California.

Tuolumne Hydraulic Mining Company.—Principal place of business, city and county of San Francisco, State of California. Location of works, Tuolumne county, State of California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 19th day of January, 1877, an assessment of Five (5) cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin to the Secretary, at the office of the company, Room 2, 528 California street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid, on the 12th day of March, 1877, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 20th day of April, 1877, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

I. T. MILLIKEN, Secretary.

Office, Room 2, 528 California street, San Francisco, California.

A NEW FEATURE.

FOUR PAGES COLORED PLATES.

One family of children having WEBSTER'S UNABRIDGED and using it freely, and another not having it, the first will become much the most intelligent men and women. Ask your teacher or minister if it is not so, then buy the book and use and urge its use freely.

"THE BEST PRACTICAL ENGLISH DICTIONARY EXTANT."—London Quarterly Review, October, 1875.

THE NATIONAL STANDARD.

PROOF—20 TO 1.

The sales of Webster's Dictionaries throughout the country in 1875 were 20 times as large as the sales of any other Dictionaries. We will send proof on application, and such sale still continues.

More than THIRTY THOUSAND copies of Webster's Unabridged have been placed in as many public schools in the United States, by State enactments or school officers.

Can you better promote the cause of education and the good of the community than by having a copy of Webster's Unabridged in your family and trying to have a copy in each of your schools?

PICKERING ENGINE GOVERNOR.

VALLEJO FOUNDRY, October 17th, 1876.

Messrs. NEYLAN & YOUNG, San Francisco,

Agents for "PICKERING GOVERNORS."

Gents:—The 10 two-inch Improved Speed Adjusting Governors I bought of you this
year for my patent Straw Baling Threshing Engines give splendid satisfaction. They
far surpass for regularity of speed any Governor that I have ever seen, and I have
seen all the best kinds; I have seen the main belt fly off the pulley several times this season
while threshing, and the engineer did not discover it, so perfectly was the speed main-
tained, until he was told of it; I consider something wonderful; I consider the Gov-
ernor absolutely perfect, so far as speed is concerned. I bought and put on to one of
my engines a Shive Governor, to see which was the best, and after one season's trial I
have no hesitation in saying they are superior to any other Governor that I have seen or
used. I wish you would send me the lowest price that you can furnish 25 Governors for
next season's engines. Yours respectfully, J. L. HEALD.

The only Governor that has received awards at each of the International Exhibitions.
American Institute Fair, New York, 1865, Two Medals; Mechanics' Institute Fair, Bal-
timore, 1865, Silver Medal; American Institute Fair, New York, 1869, Two Medals;
International Exposition, Paris, 1867, One Bronze and Two Special Medals; In-
ternational Exposition, Vienna, 1873, Medal of Progress and Decoration;
International Exhibition, Philadelphia, 1876, Medal and Diploma.

States.****\$1,000 Challenge Ore Feeder,****AWARDED FIRST PREMIUM****At the Tenth Industrial Fair of the Mechanics' Institute.**

It may be considered as now fully demonstrated, by careful and long-continued experimentation, that the plan upon which a perfect ore feeder must be constructed is that of the carrier, and not that of the shaking table. Uniform and accurate feeding is not possible upon the latter plan. The ore must be evenly carried, upon a steadily advancing plane or table, to the line of discharge, and there simply dropped. Spasmodic or jerky contrivances will not answer the purpose.

REFERENCES.

A letter received from the Julian Mill, Newcastle, says of the Carrier Feeder: "It is the most perfect Feeder we have ever seen; don't see how any mill can do without them."—A letter from Mr. C. C. Belding, of Amador County, speaks in the highest terms of them. Two of the machines were shipped to the Bunker Hill Mill, also Gover Mill, Amador County. Mr. Stevenson, of Boston Mill, Gold Hill, Nevada, says they are the best Feeder he has ever seen. —Soulby Mill, Tuolumne County. —California Company, Nevada City. —Omaha Gold Mining Company, Grass Valley. —St. Patrick Mill, Placer County.

\$1,000 CHALLENGE.**Backward in Coming Forward.**

C. P. Stanford Fails to Come to Time on the Challenge of \$1,000 to Test the Merits of His Ore Feeder as Against Mine. The Challenge is Still Open to Him or any one else. GENTLEMEN, Put up or Shut up.

A letter has been received from the Crescent mine, Plumas County, in which it states that the Tulloch is a failure as against the \$1,000 Challenge Feeder of Hendy's.

We warrant the machines to give perfect satisfaction, and to be a better and more durable Feeder than any other in the market, and will sell them as cheap as any other of its class.

TWO MEDALS OF HONOR.

TWO CERTIFICATES OF THE HIGHEST MERIT.

Of Philadelphia, offer for sale through their agent in San Francisco,

**Asbestos Steam Packing, Asbestos
Boards and Asbestos Steam Joints,**

All manufactured from the pure utilized Asbestos Patent Fiber, and under patents granted to J. S. Rosenthal. The packing is in all sizes from one-quarter to three inches in diameter, round, and free from all grit or mineral matter. The non-utilized or crude Asbestos, manufactured by some parties into packing, is impure and gritty, liable to injure the piston rod and should not be used. The packing made under the Rosenthal patents is of pure utilized Asbestos fiber, and a very superior article and entirely different from the so-called Asbestos packing heretofore offered for sale. It is compact in form, will not fuzz or disintegrate, and will wear much longer than any other kind of packing. The indestructible, expanding, contracting and lubricating qualities of Asbestos are now universally recognized, and packing made from it is peculiarly adapted for steam engines and pumps.

ASBESTOS PATENT FIBER BOARD.

This is the champion non-conductor, to prevent radiation of heat and condensation of steam, as covering for marine, stationary, or locomotive boilers and pipes, and for lining wood-work, where exposed to great heat. It is light, flexible, is not disturbed by vibration, and will not char or crumble. The sheets are 30 by 44 inches, of any desired thickness, and are easily applied.

ASBESTOS PATENT FIBER STEAM JOINTS.

Indestructible by fire or water, expands and contracts in a desirable manner, adjusts itself to any rough point, is cheaper than rubber, and in all respects a superior article. PURE ASBESTOS FIBER for packing steam governors and other purposes. All these goods are extensively used in the Atlantic States and give general satisfaction.

They have no superior. The casing is made in sections, so as to be easily accessible. They run easily, not rapidly, and the perfect contact of wings gives a uniform and powerful blast.

PALMER, KNOX & CO.,**Nos. 19 to 25 FIRST STREET, San Francisco, Ca**

"AMES" CELEBRATED PORTABLE & STATIONARY ENGINES.

This cut illustrates some of the important advantages of our "Portables." As regularly made, the Engine may, at pleasure of owner, be used on top of Boiler, or detached from it, as shown in cut, thus combining the adaptability of either form for any location. It will be necessary to send us a sketch, showing relative position of Engine and Boiler, and their distance apart, when intended to be run "stationary," in order to send with them suitable connecting pipes, which will be charged for according to extra quantity required over that furnished with the "Portables."

The boilers are of the Locomotive Pattern, which requires no setting, and is made of such material and proportions, and so arranged as to insure safety, durability, and the greatest efficiency for the amount of fuel consumed.

The shell and tube sheets of boiler are of the best Pennsylvania iron, of proper thickness to secure strength, while we take extra precaution, at an increased expense, of making

the furnace of the best solid fire box plate, which has never heretofore been used in portables on account of its high price. We prefer, however, to make less money, and produce a really first-class article, safe and sure beyond peradventure, than to increase our profits by using cheaper material. The tube sheets are also selected from iron of proper strength and thickness, according to the diameter of the boiler. The Tubes are the best American lap-welded. Great care is taken in bracing the furnaces at the sides, as well as the top and bottom, in the manner adopted by the best locomotive builders.

We would call especial attention to the great improvement in the form of our Furnaces, obtained by extending around them a water space of ample size and curved form, its under side forming an ash pan, and allowing the water to circulate freely, thus preventing sediment from accumulating and adhering, as it does in the ordinary form of locomotive boilers, in that part of the furnace below the grate.

"Ames" Portable Engine and Boiler Erected as a "Stationary."

The Engine is of the horizontal style, and is made with a bed plate, from entirely new and improved patterns, designed with a view to elegance, simplicity, convenience and strength. It is built entirely separate from and independent of the boiler, and can at any time be used as a stationary by obtaining the necessary additional length of steam and exhaust pipes. In our portables it is placed on the saddles on the top of the boiler, and secured with bolts.

Particular attention is paid to boring the Cylinder accurate and smooth, and to fitting the Piston and Valve. The Piston is of the most approved locomotive pattern, fitted with metallic packing rings, which are adjusted by steel springs of proper proportion, regarding tension, elasticity and strength.

The Slide Valve and its face are made perfectly true and steam tight, and it is constructed with the proper amount of lap to develop the most approved data of expansion that has been proved by numerous experiments to point the correct working of the engine, in relation to the use of steam, with greatest economy and efficient y.

This cut, taken from the "pump side" of No. 2 Ames Portable Engine, gives a good idea of the appearance of the sizes from five to 20-horse power. Trusting that it will convey a favorable impression as to the style of our engines, we would say as to material, that we use only the best; as to workmanship, that we do not claim any extra polish for external show, but do claim accurate and fine finish to all the working or wearing parts; we also claim that the boiler, steam and exhaust passages, and other vital points, are scientifically proportioned in accordance with the best experience and the use of the Steam Engine Indicator; also, that as we make a specialty of Portable Engines, we can sell a better and larger engine

for less money than those who do not confine themselves to any particular article of manufacture. We will not attempt in this space to enumerate the uses to which our engines have been applied, but assert that no engine surpasses them in adaptability to any work or location.

We are also Agents for Ames "Hero" Vertical Engine and Boiler, a new style of Semi-Portable, which we feel confident will meet a want long unsupplied, viz: An Engine and Boiler both efficient and durable, economical in fuel as well as in space occupied, and a thorough, serviceable and well constructed Engine and Boiler at a very low price. The Boilers are made from the best material, and subjected to a test of 150 lbs. pressure to the square inch, besides a careful and satisfactory steam trial with the Engine erected thereon. Price, for six-horse power, \$600. Address,

Number 8.

Hoe's Printing Press.

We present on this page an engraving of the large web perfecting press exhibited at the late exhibition by R. Hoe & Co. of New York. The history of this type of press begins in 1835, when Sir Rowland Hill, who became famous for his advocacy of penny postage in Great Britain, obtained letters-patent for a web perfecting press; that is, a press capable of printing a roll of paper on both sides, and cutting and piling the sheets. The difficulties experienced in this machine were owing partly to the use of conical type, and partly to the difficulty of disposing of the printed sheets. In 1853, Victor Beaumont, of New York, patented the serrated cutting

speed. The first pair of cylinders, over which hangs the roll of paper, consist of one type and one impression cylinder. Here the first side of the paper is printed. The second pair, printing the second side, consist likewise of one type and one impression cylinder; but the latter is below the former, and is of much greater size, so that the set-off from the fresh ink shall not fall continually on the same surface of the blanket. In point of fact, there is only every fourth sheet which touches the same part of the blanket, which has, therefore, time to dry. The tympan is movable, so that, should it get too black or become defective, it can be changed as follows: It is put up on the off-set cylinder in sections, each section having a roll at each end. At the beginning, the tympan of each section is all on one roller of each pair; and hence by unrolling that one, and rolling up the other, the change of tympan is effected in a very short

whole pushed rapidly across. These form-inking rollers are held in a small bracket operated by a small hand lever which locks the roller bearing in position, or releases it, as the case may be. The journal boxes of the large cylinders are of cast-iron, with composition bushings. The distributing rollers are operated laterally by a triple thread-worm movement. The ink is taken from the distributing rollers by two 6-inch form rollers. The first type roller is adjustable for the impression by a horizontal movement of the bearings, regulated by a screw and check nuts, while the second one is adjustable vertically by a similar device. A register or counter is fixed to the frame, and is operated from the cutting cylinder by bevel gearing and a worm movement. The whole machine stands so low upon the floor that every part of it is under the pressman's eye, presenting quite a contrast to the Walter press in this respect. An-

Home Industries.

The Pacific Chain Works.

By invitation of the proprietor we drove out to the Pacific Chain Works last week, and were highly pleased with our visit. The works are located on the corner of Iowa and Yuba streets, in the immediate vicinity of the rolling mills, rope-walk and other flourishing factories. The chain factory being the first and only one of the kind on the coast, it has had to contend with great difficulties in gaining a foothold, the proprietor having expended several thousand dollars in the enterprise, and so far without any returns. By strict attention to the wants of the trade, however, and care in working up only the best quality of iron, the business is fast de-

THE NEW HOE PRINTING PRESS.

blade set lengthwise in one of a pair of cutting cylinders, having elastic surfaces inserted to hold the paper on each side of the cutting blade when the sheet is cut from the web. To this device is largely due the success of all web perfecting presses. To France, however, belongs the credit of the invention which made such presses of practical value. A French inventor, in about 1850, devised the process of stereotyping with flexible papier-mache matrices, rendering it practicable to cast the type plates to fit the cylinders, and leaving but little to accomplish save the sufficiently rapid disposal of the printed sheets.

The press illustrated is a double machine, printing two complete papers at once, side by side. Moreover, it delivers the sheets not flat but folded. Its capacity ranges from 15,000 double to 28,000 or 30,000 single sheets per hour, according to the quality of the paper. The roll of paper is 52 inches wide.

The design of the press may be described as consisting of pairs of cylinders set in a massive framework four inches thick, compact and plain, having no oblique angles, but running either vertically or horizontally, as the case may be. To this construction, no doubt, is due the absence of jar, noise or vibration, which is a feature of this press even when running at high

space of time. The tympan-sheet is composed of muslin, there being ten yards in each section. From the second pair of cylinders the sheet passes to the third pair, which act as the cutting cylinders, the lower of which has inserted rubber jaws to receive the edge of the knife, which is provided in the upper roller, and operated by a cam movement so as to project the blade to perform its cutting duty and recede for the rest of the revolution. The sheet is not entirely cut in two, there being left small uncut sections about one-quarter of an inch wide, which have just sufficient strength to hold the paper together until the tapes take hold of it and conduct it to the first folding cylinder, which folds each paper lengthwise. During the passage of the paper from the first to the second folding rollers, it is, for single sheets, cut across the width of the newspaper. After leaving the first folding rollers, the sheets are, by a simple spear-shaped switch, divided alternately between the upper and lower rollers, two papers to the lower and two to the upper alternately; and by this means the folder runs at but half the speed of the press, which gives to the folding machine a capacity equal to that of the press.

For putting the lower form-inking rollers in place in the press, there is provided a small traveling carriage, upon which the bearing of one end of the roller may be placed, and the

other and notable feature is that the plates, rollers and smaller parts can be taken from the press at the sides and without ascending any steps. This is a great advantage to the printer. The workmanship throughout is of the first quality; the bearing marks show good fitting. The junction of collars, etc., with the faces show the truth of the work. The cut gears, which are covered to avoid accidents, work smoothly and show even contacts. The shafts of the impression rollers, type rollers and folding cylinders are of steel; and all the links and connections are case-hardened, so that durability is assured.

MAP OF THE BLACK HILLS.—We have received from A. L. Bancroft & Co., 721 Market street, a map of the Black hills, showing the mining districts and the seat of the Indian war. The map is a small pocket one and was drawn by A. C. Bierce from surveys ordered by the War Department. It is especially valuable as giving the location and direction of all the streams, large and small; the trails from and to different points. Those intending to make a trip to the Black hill regions would do well to provide themselves with one of these maps. They are sold for 50 cents.

THE amount of import duties paid at this port last week was \$113,367.

developing into what promises to be one of the leading industries of the city.

The recent reduction in the price of iron in the market, together with the enhanced value of currency, enable the works to compete in price with the East, which heretofore they have not been able to do. They are now engaged on an endless chain made of one and one-half inch iron, which, when completed, will weigh over 10,000 pounds. It is designed for a milling company on Puget sound, and intended to fit in a wheel.

In another part of the works, a lot of three-quarter inch coil chain was being made for one of our local iron dealers, while at the entrance some 8,000 pounds of cable chain was being delivered to one of our leading ship chandlers. The Pacific Chain Works were established and are still owned by James E. Gordon, wholesale dealer in hardware, 254 and 256 Market street and 8 and 10 Front street, to whom all orders or correspondence should be addressed.

THE papers state that there are more men out of employment in Virginia City at the present time than there have been at any time within the past 12 years.

A CORRESPONDENT at Pera telegraphs that peace with the Principalities is considered certain.

CORRESPONDENCE.

Mining vs. Speculative Robbery.

[Written for the Press by ALMARIN B. PAUL.]

As all the readers of the PRESS well know, I have persistently advocated legitimate mining. I cannot understand how or why it is that so much capital will be put up for speculative robbery, and so little comparatively for honest development of our mines. The time was in California when all regarded mining as a business to be pursued for its legitimate reward; but at this stage of our industry, there seems to be more money for running holes in the ground and a chance to "speculate" than for honest work. The time was even in Nevada, on the Comstock, when investments were made for development and its merited gain. Then general prosperity pervaded all the communities; then, however, there were fewer very rich men. The business of mining, legally considered, wants a good overhauling, and to build up the mining localities of our State the legislative members of the mining counties must do it.

Our incorporation laws as they stand to-day are made to protect inside thieves from punishment, and to form an impregnable wall around "rings," and not as laws to protect the great body of stockholders. This "ring" business and speculative mining is carried on by too many of our mining operators of San Francisco, who make it a game of heads I win and tails you lose. Mining is one thing, gambling another; and to stop both gambling and robbery is what our next Legislature must start in strongly for, and then all our mining localities will loom up into importance, as capital will not all be absorbed in "California street" mining.

From our original system of "honest" mining, where men chose their partners and worked and thrived on honor and received their just dividends, incorporations were inaugurated and deservedly became popular. Trustees were then men in trust, they accepted the responsibilities and acted accordingly; but soon trusteeship is wielded by capital and becomes a business, and they become too often the agents of the few, and not the protector of the many.

Later in the day, to clothe this authority with more gullible dignity, the title of Director is introduced, and with it a new code which for deficiency is unequalled, and which operates as a brazen swindle on the unsuspecting stockholders. In addition, as an important feature of too many Boards of Directors, in the back office sits "Simon," the dictator, who jingles his little bell and send his orders to "manipulate," and the Directors, as obedient servants, or worse, sycophantic slaves, manipulate the coin out of the pockets of the outsiders into Simon's and their own, by the many ways of accomplishing this end. Sometimes by assessing, and taking the stock in at a trifle, then, by secrecy and deceptive accounts, elevate it, and if it pays they go out; and now and then by absolute swindling. What is this, honest jugglery or legalized robbery? Some people smile at it and call it smart, others wonder at it and call it theft. Some say Simon, if not his dummy Directors, should be sent to the United States Senate; others think they would better grace the workshops of San Quentin. Which is right?

The effect of such operations is, the people are robbed, and the country in honest development gets no benefit from all this outside capital, and as our laws are, Simon and his cohorts soon become capitalists and are law-proof, join possibly the Christian Association, build fine mansions, and are too often the associates of the honorable. Men are sent to the penitentiary for stealing trifles, while Simon and his cohorts steal thousands, yes, millions, rob poor men, women and orphans and yet go scot free. Should there not be better laws to regulate this business? If laws are made only for punishing the poorer and less gifted, then the prison gates had better be opened and society left to regulate itself, as we regulated it in 1849-50.

This is our advancement, and it is to be wondered at that our miners are adverse to corporations? Still the corporation system is correct, honestly conducted, as by it more capital can be aggregated and individual liability avoided, and no other system is as good; but we must have laws which are a protection to the investor of a small amount of capital as well as larger—laws that make criminals of swindlers in stock operations, and laws that will summarily punish all such. Then the miner with his mine can throw himself into the hands of capital with some safety and be benefited as well. This done, there would be more legitimate and honest mining, and every mining district have equal chance with the cities for prosperous advancement by this industry.

If the mining counties want to enhance their prosperity, this mining question must receive their earnest attention, and not merely comment on it and forget all when the Legislature meets; for this system of legalized robbery, carried on so long, has ruined thousands, and brought more tears into suffering households than would extinguish the Palace hotel were it all in flames. It has blasted character and sent more than one unfortunate to an untimely grave; besides, if all the capital that has been

squandered in the past ten years in speculative mining and ring robberies had been properly invested and honestly administered, the product of the precious metals would have been 50% more than they are to-day. I do not wish to be understood as thinking there are no incorporated companies honestly conducted; far from it; but there are too many dishonestly conducted, and one swindle does more damage than a dozen good operations can do good by way of inspiring confidence and influencing capital. There are many companies whose directors have a laudable regard for their stockholders, but they "don't amount to much;" they can't put stock up when it ought to go down, or down when it ought to go up; they are not "smart," but honest. The lines want to be drawn in such a way that companies honestly conducted have some credit for so managing the business, and not that they are to be besmeared and damaged by the rascality which now has too much sway and too little punishment.

Quartz Interests of Amador.

EDITORS PRESS:—I have been a constant reader of the PRESS for the last 10 years, and of late see but little published about the quartz interests of Amador county. It is evident from the present outlook that the county, this present year, is going to surpass in the production of bullion all its previous yields for the same length of time. The Phenix mine, at Plymouth, with its 80-stamp mill running at present to its full capacity, crushing about 140 tons per day. The quartz being of low grade, yields but a very small profit per ton. The ore body is of immense size and likely to last for some length of time. The Bonanza mine, at Drytown, never looked better. The last clean-up made the hearts of Belding & Manon feel good, and the next is to be still an improvement on the last. Crown Point is looking better, with great hopes of realizing some \$10 to \$15 per ton as a result of their first crushing. I think \$8 per ton would pay stockholders handsome dividends, if the mine is properly worked with economy and skill. The ore body in sight is sufficient to keep a 20-stamp mill running for some years. The Gover mine, with its new 20-stamp mill, ought to pay dividends soon, if the ore body is as rich and as extensive as reported. We think that this mine is put up at too high a figure, \$35 to \$40 per share, and why is it that one of the principal officials and stockholders should offer all of his stock for \$30 or less? (Have they struck a horse in their lower levels or what?) I trust all is right at the Gover. It looks, however, a great deal as if the mine was managed for the interest of a few stockholders. Amador county has enough of good mines, if judiciously managed, to make it one of the very largest gold producing counties in the State. The Bunker Hill mine does not look very flattering. The Little Amador is beginning to look better, and, if the present developments continue to improve, will yet make a good mine. The Keystone mine, one of the very best mines in the State (a close corporation, no stock for sale), turns out, with its splendid mill of 40 stamps, its regular \$40,000 per month, leaving a large margin for dividends. The Lincoln mine, at Sutter Creek, is shut down, with but little hopes of it starting up again. The Mahoney mine is running, extracting some ore on and near the surface, with what result I do not know. The Amador Consolidated keeps paying its regular monthly dividends, and will most likely keep doing so for some months longer. The quartz extracted from the mine at present comes from the old reserves above the 800-foot level and near the surface. The Oneida mine, with its mill of 60 stamps, keeps pounding away on a low grade of quartz, but an improvement is looked for in the new strike made north of the hoisting shaft. The quartz, of an average grade, carries a fair per cent. of sulphurets, and it seems strange that the management of some of these large mines, with mills of 40 to 80 stamps, such as the Keystone, Oneida and Phenix, do not go to work and erect their own reduction works (as I understand they concentrate from 45 to 50 tons each, per month, of sulphurets, that will assay from \$100 upwards). While visiting the Providence mine, in Nevada county, I learned they were reducing their own sulphurets, at a cost not to exceed \$15 per ton, and at the Washington mine, Mariposa, it did not cost them over \$10 per ton, while here a monopoly charges \$25, with no special guarantee of returns. A splendid opening for a party who is skilled in the reduction of gold-bearing sulphurets is offered in this district. AMALGAM.

NEST-BUILDING EXTRAORDINARY.—During a recent visit to Anstey, near Leicester, I saw in a box tree (about eight feet from the ground) the nest of a long-tailed titmouse, with a nest of song thrush resting immediately on the top thereof, both of this year's construction. My host could not tell me for certain which species was first in the field, but fancied that the titmouse commenced building operations. The nests of two species of such different character thus joined together presented a most curious appearance, and the sight was so novel to me that I thought an account of the same might interest some of the numerous lovers of natural history who read your paper. I may add that there was no bough or twig between the two nests to form a support, the upper one being literally built on the lower.—Exchange.

The Lady Bryan Machinery.

In an article on the Lady Bryan mine, the Gold Hill News speaks as follows of the new works:

These are eligibly located at the most advantageous point possible for sinking the shaft and working the mine to a depth of 2,000 feet or more, and the machinery will be of amply sufficient power to do this. The pumping engine is already in position, and the completion of the details and connections is being pushed forward as fast as possible. It is a new style of engine, now being adopted by the principal companies of the Comstock, and the same as that at the Belcher air shaft, the Overman, and also at the Chollar-Norcross-Savage combination shaft. Technically speaking, it is a vertical compound condensing engine, direct-acting, with inverted beam, and controlled by Davy's differential valve gear and cataraet motion. The initial cylinder is 26 inches in diameter, with eight feet stroke, and the expansion cylinder is 38 inches in diameter, with ten feet three inches stroke. The engine, however, can be controlled to any lesser length of stroke, and a greater degree of speed given if required. A condenser and air pump for creating the required vacuum in the expansion cylinder are conveniently connected, and the whole forms a very substantial and highly effective arrangement. The engine is 400-horse power, nominally speaking, yet it can be speeded up to 500-horse power if required. It was designed and built at the Risdon Iron Works, San Francisco, and put in position under the supervision of I. F. Thompson, the well known constructing engineer, who has the contract for placing the machinery of these new works. Robert Moore, son of Joseph Moore, of the Risdon Iron Works, and a master mechanic, is employed by Mr. Thompson as foreman of the job. The foundations are of solid granite, and as massive and substantial as any in this section. The pit beneath this engine, for the pump-bob or beam, is 25 feet deep, and the beam itself is 32 feet long and weighs 23 tons. It is of iron, constructed after an improved style, which gives it the strength of others which weigh double as much. The pump column, which is already in place, is 12 inches in diameter, and the pumps are of the Cornish style, two plungers and one lift, with eight feet stroke. The boilers have arrived and are now being set, and the engine will be started into operation probably in about two weeks, pumping the water out of the shaft and mine. The hoisting engine, which is of the horizontal style, with 18-inch cylinder and 27-inch stroke, is completed and will arrive shortly from San Francisco. The foundations are all ready to receive it as well as the hoisting reels and other requisite machinery, all of which will be placed in working position as soon as practicable. Everything will be new and first class in every respect, with all the latest improvements.

The Buildings.

The main building over the shaft and hoisting works is 40 feet wide by 84 feet long, very substantially constructed, and the hoisting or galleys frame at the shaft is 36 feet high, very strongly constructed of heavy California spruce timber, from Dutch Flat. The house for boiler-room, carpenter shop, etc., adjoins the main building on the north, and is 38 by 64 feet in size. A convenient blacksmith shop stands at the south side. The mill of the company stands a few rods south of the works, and a tramway leads directly to its battery from the shaft, so that there will be no expense in the way of ore transportation. Being situated on the sloping bank of the ravine, the mill is as conveniently arranged as is possible, the ore being dumped from the ore cars directly at the battery, and thence passing on a continuous downward delivery to pans and settlers, and the tailings to the blanket sluices in the ravine. Everything about this mill is first-rate, except the battery of 10 stamps. It was an old battery when it was put in, and proved to be defective and inefficient, only crushing about half what the pans can handle. With a new 15-stamp battery, which is already contracted for, the mill is capable of working 35 tons of ore per day.

The New Shaft

Is 600 feet deep, and consists of two cage compartments four and a half by five feet each in the clear, and a third or pump compartment five by six feet in the clear. It is very substantially timbered throughout, and will prove to be the most advantageous and effective outlet arrangement possible in the future working of the mine. It was commenced nearly three years ago, and openings made from it into the old mine at the 80, 170, 250 and 380-ft levels respectively. Merely the incline from the old workings was found to have penetrated to that depth, all the drifts and other explorations being above that point. A station is opened for the 500-ft level, and the water in the shaft stands now nearly up to the 250-ft level.

The Ore and Bullion Resources.

The mine has been extensively opened at the three upper levels mentioned, and although a large amount of good paying ore has been extracted therefrom, thousands of tons yet remain which can be extracted and worked with good profit. Some very rich spots and bunches of ore have been found at the 80-ft level, of the green chloride character, with free gold, and at the 170-ft level, where ore of the white Comstock character commences coming in, one of the mining reporters of the News, who was taking an examination of the mine on Tuesday last,

brought out samples which gave assays of from \$15 to \$206 to the ton, silver predominating. There are many thousands of tons of that ore in sight, and together with what is developed in the level above as well as the level below, there is ore enough in sight, and immediately available, to keep the mill running for a year or two at least. The 380-ft level has been drifted upon some 700 feet south and 250 feet north from the shaft, following the east wall, but very little cross-cutting was done. The ledge was found to be all quartz, and considerable ore of a fair grade was met with, but as further explorations and development could not be conducted to advantage, all work in the mine was stopped until the present new pumping and hoisting machinery could be procured and brought to bear in the case. The shaft cut the east wall of the vein at the depth of 400 feet, and has passed through to the west or foot wall.

Mount Hamilton.

At the time of the recent visit to our city, says the San Jose Mercury, of the members of the Lick Board of Trustees, an order was given to Hermann Brothers for maps and surveys of the Mt. Hamilton road, the mountain itself, and such other facts and statistics as would aid Capt. Floyd, one of the Trustees, who is now in Europe, to perfect his plans in the selection of the proper astronomical apparatus, glasses, etc., to be required for the forthcoming observatory. In accordance therewith the above gentlemen, Messrs. Hermann, began their work, which has just been completed, the maps having been taken to San Francisco yesterday. A reporter of the Mercury called upon the firm, and was kindly permitted to examine the notes which accompanied the maps, from which the following statements may prove of interest to others besides those immediately connected with the building of the Mt. Hamilton road and the observatory:

The approximate geographical location of the observatory peak is 120° 36' 40", longitude west of Greenwich, and 37° 21' 3" north latitude. The approximate height of the same is 4,255 feet above the sea level. The scope of the horizon from this point takes in more ground, according to Prof. Whitney's judgment, than almost any similar peak in the United States, there being no obstruction to the view from any quarter. It is remarkably free from fogs and clouds, as the Messrs. Hermann had ample occasion to observe during their last winter's stay in the mountain, when locating the road. The bearings to the most notable objects are as follows, the distances being taken, when out of our county, from the most reliable maps:

Mt. Loma Prieta, S. 35° 5' W.....	19 1/2 miles
Mt. Umuhum, S. 40° 40' W.....	19 1/2 "
Mt. Thayer, S. 51° 15' W.....	19 1/2 "
Black Mountain, S. 87° W.....	27 1/2 "
Mt. Pouchet, S. 83° 35' W.....	6 "
San Jose Court House, N. 80° 50' W.....	13 1/2 "
Calaveras Point, on San Francisco Bay, U. S.	
Triangulation Station, N. 60° W.....	24 "

Mt. Santana, S. 37° E.....	35 "
Murphy's Peak, S. 6° 25' W.....	15 "

None of these points reach the altitude of Mt. Hamilton. Of those within a radius of 20 miles only the Loma Prieta reaches 3,800 feet; Umuhum, 3,500 feet; Thayer, 3,550; Black Mountain, 2,800. All the rest are between 1,500 and 2,500 feet. Of the further peaks, only Mt. Diablo reaches 3,856 feet, but this is too far to come into consideration.

The formation of Mt. Hamilton, as of all the near surrounding ridges, is of trap-rock. The high points, not worn down by the atmosphere and the action of the rain, are therefore very hard as soon as you remove the upper crust. At the building of the road they struck this hard rock at six or seven points on and near the cone, with a good prospect of finding it continuous and getting harder in the same proportion as you get deeper. It has broken through the older formation at several points near the base of the mountains, where it shows the same character, only intensified. At the top it appears as a greenstone porphyry, with small feldspar veins, exceedingly hard, without any defined strata, but in huge boulders, more smooth and generally flat on one side, cemented together by other material, less hard and easier to work. At a great many places the metamorphic slate, uplifted by the latter upheavals, shows in considerable bodies, one of them being on the south side of the Observatory peak, and nearly opposite one of the hardest points of the porphyry. A well tempered drill will cut from two to four inches in one sharpening. The cost, therefore, of cutting down the top of the peak will be very considerable, and will increase, at an increased ratio as you go down from the upper to the lower contour line. Messrs. Hermann think, however, that a large proportion of the rock blasted off can advantageously be used to widen the space for the foundation, by laying it up in cement on a well prepared lower base.

As a meteorological station, Mt. Hamilton, no doubt, stands first in the list of our coast peaks, and as such will be of great immediate practical use after the establishment of the Observatory.

THE cartridge manufacture in the United States is said to be larger than that of any other country, and reaches at present 2,000,000 per day.

MECHANICAL PROGRESS.

Friction and Wear of Bearings.

M. C. Kunzel has tabulated the results of experiments made on the effects of friction between various substances, which are reviewed by the *National Car Builder*. The heat produced, (other conditions being equal) is in proportion to the hardness of the substances; and, on the other hand, the greater the difference in the hardness of two substances rubbing against each other, the less the heat produced by the friction, and the harder of the two heats more than the other. If friction takes place between glass and cork, the amount of heat received by the two respectively is as seven to one, and between bronze and cork, four to one.

For durability alone bearings should be of metal as hard as that of the arbors which they support, but considering the wear of the latter, the former should be as soft as possible. In practice, however, certain precautions are to be observed; the bearing must not cut the arbor, and it must wear as little as possible; it should not get hot even when lubrication fails; and, lastly, it should possess resistance enough to bear all the shocks that fall upon it without being deformed or broken. The alloys of copper and tin generally in use are rarely homogeneous, with the exception of that which contains 82 to 83 parts of copper to 17 to 18 of tin. When there is less tin in the composition, granulation takes place during cooling, which alters the homogeneity of the alloy and causes the cutting both of bearing and arbor. When an alloy of copper and tin sets slowly, the first part consolidated is a very soft alloy not containing more than 7 to 10 of tin. This forms, as it were, the shell of the bearing, while the hard alloy, containing 17 to 18 parts of tin, sets afterward and fills up the shell. When a bearing thus formed is in use the soft alloy soon gives way, and the hard grains within attack the arbor and are often torn out and carried away when grease fails.

A good bearing should be the very opposite of the above; its shell should be very hard and durable, and the interior filled up with a softer composition. This result is attempted to be obtained by fusing together several alloys of different compositions and degrees of fusibility, so as to produce by cooling two given alloys, but the operation is delicate and the result uncertain. Phosphorus bronze succeeds best in this way; the shell is then entirely formed of very hard bronze and the interior of a soft alloy of copper and tin. The bearing may then be considered as a series of layers of soft metal enclosed in a casing of metal almost as hard as the arbor itself. The microscope reveals this disposition very evident, and if one of these bearings be carefully submitted to heat to cause the soft metal to run, the rest remains in the form of a spongy mass.

Demagnetizing Tools.

The following from the *Art Journal* will be of interest to workers with fine steel tools: A correspondent, in your journal, asks how to remove the magnetism from a kit of tools. So far as the actual experience of the writer goes there is but one "sure cure," that is to heat the tools to a red heat. If they are plain, common tools, this will be the easiest and quickest way. The time expended is not necessarily lost, as there will be an opportunity to harden and temper them specially for the use to which they are put. A large share of common tools are very far from being properly tempered. But where tools are such as would be injured by the heating, or which the owner does not feel competent to harden and temper properly, there is another way to remove the magnetism. The writer has never tested it himself, being very careful not to have any occasion for the use of such a process. But it is strongly recommended by others whom he knows to be trustworthy and experienced mechanics. It is to take the common bar or horse-shoe magnet, and magnetize the tools by rubbing it over them lengthways, either in actual contact or very near to them, until they are well charged, then reverse the direction of the motions of the magnet and take the magnetism out. The object of the former part of the operation is said to be to make sure of the polarity of the article, so that the reversed motions will be certain to take the magnetism out, because the former had put it in. This seems reasonable, for everybody has magnetized his jack-knife with a poker, and demagnetized it by reversing the process. The only apparent difficulty would be to stop just at the right time, instead of going on and getting the article re-magnetized, only with the poles changed. But this could be effected by frequent tests, dipping the piece into clean, fine, dry iron filings, and the moment they ceased to be attracted at all, the operation would be considered completed.

MAGNETIZING WHEELS.—A Swiss inventor envelops the driving axle of locomotives in coils of insulated copper wire, and by the passage of an electric current converts the wheels into powerful magnets, with increased adhesion to the rails. This is charming, with the exception that numerous patents have already been taken for the same thing, and that it will not and could not work with any practical effect. The Swiss gentleman referred to has brought out something at once new and good.

Steel Experiments in Russia.

An English paper says that it is proverbial in Sheffield, and other centers of steel production and manipulation, that much remains to be learned in relation to that material. There are, in fact, phenomena and peculiarities observable about it, while in process of conversion and refinement, which baffle the judgment of the most practiced operators to understand. The same results by no means follow the same modes of treating steel in its gestatory stages; and the best makers freely admit that they cannot guarantee to supply, in continuity, steel of uniform grain and texture. In the midst of this uncertainty a Russian experimenter on steel, Mr. Chernoff, has published lately, at St. Petersburg, a pamphlet on the whole subject. The author states that "if steel melted in a crucible is constantly kept in violent agitation while cooling—agitation violent enough to keep all its particles in motion—then the cold ingot produced will have a very finely crystallized structure; if, on the other hand, the steel is allowed to cool in perfect quiet, then the resulting casting will consist of large, well-developed crystals. The appearance of these crystals, and generally the tendency to crystallize under such circumstances, will depend on the purity of the steel." Starting from this remarkable, but apparently well established base, Mr. Chernoff concludes that liquid steel really obeys the laws which regulate the crystallization of fluids. It is probable that chemists, at least, will agree to the truth of this deduction, for they know that if they wish to obtain crystals from a solution, the latter must be kept in perfect quiet. The author of the pamphlet asserts, too, that in the course of his long-continued experiments he has discovered that steel, when heated above a certain temperature, as to a dark cherry red, loses its crystalline structure and becomes amorphous. If, again, from this point it be allowed to cool undisturbed, it will become once more crystalline, unless it be hammered during the evolution of heat from it, when its fracture will exhibit its amorphous tendencies once more, and present a fine silky texture.

NEW AERIAL MACHINE.—Experiments were made recently at Chatham, on the Great Lines, with an invention of Captain M. T. Sale, R. E., who is Secretary of the Royal Engineer Committee. The invention is a new aerial machine, to be used for discovering the position, etc., of an enemy's camp at night. The machine consists of a light framework covered with loose canvas, which becomes filled with air, and thus the machine is kept aloft. When at a proper height a parachute provided with fire-balls is sent up the line holding the machine; and, on reaching the machine, the parachute explodes, and the fire-balls are discharged, and thus the surrounding country is lighted up for a considerable distance, and the position of an army would be shown. The trials proved very satisfactory, in spite of the bad weather which prevailed; and further experiments will be made under more favorable circumstances. The trials were made in the presence of Major Maquay, instructor in field fortifications, and many other engineer officers.

FLUID COMPRESSED STEEL.—The *Polytechnic Review* notes that, speaking at the Iron and Steel Institute on the application of the hydraulic power in forging, Sir Joseph Whitworth stated that his firm had recently completed two twin screw shafts for the *Inflexible*, 283 feet in length, 17 inches in diameter, and cast with a nine-inch hole through them. These shafts were made of compressed steel and weighed 63 tons, instead of 97 tons, if made of iron—a reduction permitted by the great strength of the compressed steel. He further stated that on applying the hydraulic pressure, a column of metal is reduced one-eighth in less than five minutes—a remarkable indication of the effect of pressure in expelling air-cells. The strength of the shaft was 40 tons to the square inch, and its ductility or power of extension was 30% of its length. By using compressed steel, the driving round of 34 tons was saved during the whole life of the engines.

PHOSPHOR BRONZE WINDING ROPES.—According to the *Mining Journal*, M. J. Manne, the manager of the Phosphor Bronze Works, at Val-Benoit, Liege, exhibited a winding rope made entirely of this alloy. Phosphor bronze ropes have the advantage of offering a great resistance to strains of traction, of being very pliable and inoxidizable and of resisting any attack of corrosive water, while the wear due to the contact of the wires is less than in other metallic ropes; they also preserve their pliability after wear. These phosphor bronze ropes are used in Belgium, at the Bois-du-Luc, Horloz and Courcelles-Nord collieries among others.

A TUBE STRETCHER.—Mr. J. T. Connelly, of the National Locomotive Works, is a man possessing no little genius. Among several indispensable inventions he has made in the manufacture of steam boilers, will be found a tube-stretching machine, that not only does away with welding boiler tubes, as heretofore, which is a very lame way of repairing flues, when once too short. By this invention a flue can be drawn out six or eight inches longer, by a common laborer, in less than one-half the time taken by a skilled workman in welding, and makes the job ten times better; in fact makes the flues as good as new.—*Connellsville Monitor*.

SCIENTIFIC PROGRESS.

Experiments with the Telephone.

We have formerly given a description of an apparatus by means of which Prof. A. Graham Bell expected to succeed in telegraphing sound. His experiments have met with wonderful success, and an exhibition lately given is reported by the Boston papers. From them we draw points of interest: The experiment was made from the office of the Boston Rubber Shoe Company, where a large company of gentlemen had assembled at noon on Wednesday. The wires used were those of the company, running from the office to the residence of Mr. Converse, in Malden, six miles distant. Thomas A. Watson, the professor's assistant, officiated at Mr. Converse's house. Stationed at the Boston end of the wire, Prof. Bell requested Mr. Watson to speak in loud tones, to enable the entire company to at once distinguish the sounds. To show that loud speaking was not essential to intelligibility, Mr. Bell explained that soft tones could be heard even more distinctly than loud utterances, and in confirmation of this Mr. Watson began speaking in turn with each member of the company, and after the efficiency of this method had been proved, he informed the assemblage that gold had closed the previous evening in New York at 105½. The desire for conversation having become general, Mr. Watson was plied with questions, such as "Is it thawing or freezing at Malden?" "Who will be the next President?" etc. It was remarkable that Mr. Watson was able to distinguish between the voices at the Boston end, he calling at least one gentleman by name as soon as the latter commenced speaking. A lady at the Malden end sent the company an invitation to lunch per telephone, and an appropriate response was made by the same medium. At length the company were requested to remain quiet while a lady at the other end conveyed to them the sweet strains of music. The assemblage thereupon listened with rapt attention while the lady sung "The Last Rose of Summer." The effect was charming. Possessing as the fair cantatrice does a voice of exquisite sweetness, the sounds penetrated into the Boston end of the telephone with a distinctness equal to that attainable in the more distant parts of a large concert-room, and a unanimous vote of thanks was sent by the handy little instrument which had procured for the assemblage so agreeable an hour. Among those present were electricians and gentlemen occupying prominent positions on our Western railroads, and one and all expressed the conviction that the telephone was destined to achieve the greatest possible results.

The telephone, in its present form, consists of a powerful compound permanent magnet, to the poles of which are attached ordinary telegraph coils of insulated wire. In front of the poles, surrounded by these coils of wire, is placed a diaphragm of iron. A mouthpiece to converge the sound upon this diaphragm substantially completes the arrangement. As is well known, the motion of steel or iron in front of the poles of a magnet creates a current of electricity in coils surrounding the poles of the magnet, and the duration of this current of electricity coincides with the duration of the motion of the steel or iron moved or vibrated in the proximity of the magnet. When the human voice causes the diaphragm to vibrate, electrical undulations are induced in the coils environing the magnets, precisely analogous to the undulations on the air produced by that voice. These coils are connected with the line wire, which may be of any length, provided the insulation be good. The undulations which are induced in these coils travel through the line wire, and passing through the coils of an instrument of precisely similar construction at the distant station, are again resolved into air undulations by the diaphragm of this instrument.

The simplicity of Prof. Bell's system will be apparent when it is known that the voltaic battery is entirely dispensed with. All that is required for communicating between the most distant points are the instruments and the telegraph wire, the latter taking the place of the speaking tube, and the former that of the mouth-piece.

A TALKING MACHINE.—The Marquis of Salisbury and Mr. Farjeon have recognized the merit of the writing machine, but we should like to have Mr. Carlyle's opinion of the newly invented talking-machine. We hear that after 30 years, which the historian of the Great Frederick will probably think might have been better employed, a clever gentleman has succeeded in producing an apparatus consisting of a table with pedals, an organ, bellows, and a keyboard. In the center is an elaborate arrangement, representing the human lungs, larynx, glottis and tongue. At the conclusion of the exhibition in the Grand hotel, Paris, it spoke "a piece" as follows: "I was born in America. I am speak all languages, and I am very pleased to see you. I thank you for your visit." There is already too much talk in the world, but yet this machine might be made useful. It would, for instance, be invaluable at railway stations where porters roar out the name of the place in tones equally loud and unintelligible. A good talking machine would be a vast improvement on the inarticulate porter.—*Iron*.

Hydraulics of the Ancients.

Father Secchi has written a letter to the French Academy of Sciences on the "Hydraulics of the Ancients." The monuments he mentions have been mostly discovered by him in the environs of Rome. The first mentioned by him is an aqueduct built at Alatri, 200 years before the Christian era. It is an inverted siphon, its lowest point being 101 meters below the orifice from which the water flowed into the town; so that it sustains at its bottom a weight of at least 11 atmospheres. The pipes of this aqueduct are of earthenware, buried in a thick bed of concrete; they were very firmly joined together along a length of seven and a half miles. This work seems to have been the model on which Vitruvius founded his description of siphon aqueducts. The second remarkable relic of antiquity found at the same place is a complete system of drainage, composed of enormous porous stone-ware pipes, a meter in length, 14 centimeters in diameter, and only two in thickness. This was done to dry up a plain intended for military maneuvers. Next come inclined planes expressly laid down on substantial foundations and near the top of a mountain, in order to collect rain water on a large surface, with a basin to purify it, and cisterns to preserve it. This was done to provide the town of Segni with potable water. Then follow contrivances of the ancients for turning the water filtering through porous ground into the aqueducts by turning the clayey strata to account. They used also to rid water of its carbonates of lime by boiling, then cooling it again by applying snow to the outside. They likewise had an ingenious way of cooling their "aqua tepular," which was too warm for drinking after it had been brought over to the Capitol. Father Secchi has discovered the spring whence it came, and found that it marks 18° Cent.—64° Fah.—in winter. The Romans used to mix it with water from the Julia, which only marked 11°. The other spring, now called "Preziosa," issues from an old volcanic crater.

Late Theories on the Earth's State.

Is the inside of the earth fluid or solid? Even in a such an apparently simple question as this we are still in some degree of doubt. You may think this is strange, because we find volcanoes throwing out lava, which is liquid rock, and because we find much other geological evidence to show that solid rocks, such as basalt and trap, have been protruded as molten masses within recent geological epochs; but it has recently been shown by Mr. Mallet that the fact of volcanoes throwing out liquid rock may not be inconsistent with the view that the earth as a whole is solid. Mr. Mallet's investigations go to prove that this liquefaction of the rocks which we observe may be produced at no very great depth from the earth's surface by the shifting and rubbing together of the rocks, owing to cracking due to the alteration of the temperature, just as boys at school rub a button on the bench until it is hot, when they often place it on their neighbor's cheek. Applying the laws of the mechanical theory of heat to this problem, Mr. Mallet believes that the friction of the rocks, caused by the cooling of the earth and the consequent shrinkage, is a sufficient and satisfactory explanation of the occurrence of the high temperature of volcanic action.

Sir Wm. Thomson, also, than whom no one is more capable of expressing an opinion, decides in favor of the earth's solidity. He tells us in his address to the Physical Section at Glasgow, that the conclusion concerning the solidity of the earth originally arrived at by Hopkins is borne out by a more rigorous mathematical treatment than that physicist was able to apply; so that the idea of geologists, who were in the habit of explaining underground heat, ancient upheavals, or modern volcanoes by the existence of a comparatively thin, solid shell resting on an interior liquid mass, must now be given up as untenable.—*Professor Roscoe*.

POCKET MICROSCOPE.—An ingenious English optical instrument maker has just invented a pocket microscope, upon which scientific writers are conferring much praise. The new lens consists of three lenses, the interior grooves of which are almost transparent; they are lined by transparent cement, which has a refracting index corresponding very nearly with the glass. In this way no light is lost by the refraction from the surfaces of the curves. The peculiarities of this remarkable invention are that it focuses three times, as far from the object under examination as either the Stanhope or Codrington lenses. By this means scientists and others using the microscope can examine opaque objects as well as transparent ones, as the light can be conveniently allowed to fall upon them at any required angle, as the definition is exceedingly sharp.

AN APT COMPARISON.—The late M. Ste. Claire Deville was one day discussing with a famous anatomist the subject of the advance of knowledge. "After all," he said, "you have made great advances; but don't you think you are very like the hackmen, who know all the streets, but haven't the remotest idea of what is going on in the houses?"

THE ENGINEER.

Government Tests of Iron and Steel.

The President has sent the following message, upon the subject of testing iron and steel, to Congress:

I desire to call the attention of Congress to the importance of providing for the continuance of the board for testing iron, steel and other metals, which, by the sundry appropriation act of last year, was ordered to be discontinued at the end of the fiscal year. This board, consisting of engineers and other scientific experts from the army, the navy and from civil life—all of whom, except the Secretary, give their time and labors to this object without compensation—was organized by authority of Congress in the spring of 1875, and immediately drafted a comprehensive plan for its investigations, and contracted for a testing machine of 400 tons capacity, which would enable it to properly conduct the experiments. Meanwhile the subcommittee of the board have devoted their time to such experiments as could be made with smaller testing machines already available. The large machine is just now completed and ready for erection at the Watertown arsenal, and the real labors of the board are therefore just about to be commenced. If the board is to be discontinued at the end of the present fiscal year the money already appropriated and the services of the gentlemen who have given so much time to the subject will be unproductive of any results.

The importance of these experiments can hardly be over-estimated when we consider the almost endless variety of purposes for which iron and steel are employed in this country, and the many thousands of lives which daily depend on the soundness of iron structures. I need hardly refer to the recent disaster at the Ashtabula bridge, in Ohio, and the conflicting theories of experts as to the cause of it, as an instance of what might have been averted by a more thorough knowledge of the properties of iron and the best modes of construction. These experiments cannot properly be conducted by private firms, not only on account of the expense, but because the results must rest upon the authority of disinterested persons. They must therefore be undertaken under the sanction of the Government. Compared with their great value to the industrial interests of the country, the expense is very slight. The board recommend an appropriation of \$40,000 for the next fiscal year, and I earnestly commend their request to the favorable consideration of Congress. I also recommend that the board be required to conduct their investigations under the directions of the Secretary of War, and to make full report of their progress to that office in time to be incorporated in his annual report.

U. S. GRANT.

Executive Mansion, Jan. 30th, 1877.

The *Iron Age* says: This is timely. The importance of the work is great, while it is of such a character that we can only look to the Government to carry it on. Every day demonstrates the need we have of a greater knowledge of the properties of iron and steel when manufactured in large masses. Materials which show most extraordinary powers of endurance in one form are often weak in another; changes of structure take place and a variety of phenomena occur for which we are at a loss to account or interpret. The labors of the board will give us what we want, and there is little doubt but the needed funds will be appropriated by Congress.

The East River Bridge.

Chief Engineer Roebling has presented his annual report to the trustees. The following were the principal facts: The small quantity of stone yet remaining to be put on the anchorages and towers cannot be laid until the cables are completed. The masonry constitutes one-half of the whole work, which is therefore about half done. The machinery for delivering the stones on top of the towers is so perfect that it costs no more per yard to lay the top courses than the bottom ones. The arches of the Brooklyn tower were completed in the spring of 1874. The keystones, blocks weighing 11 tons, were fitted in without trimming, which showed great accuracy of measurement at the quarry and in the adjustment of the joints. On the completion of the tower the saddle and saddle-plates, which are twice as heavy as those at Cincinnati, were raised and put in place without accident. The resistance offered by the weight of the masonry on the plates against the upward pull of the chains affords a margin of safety of two and one-half times. This figure seems small compared with those of the main cables, where the margin of safety is about six times. But in the anchorage only two factors have to be considered—granite and gravity. The anchor chains are so disposed as to form the quadrant of a circle from a point of 20 feet above the anchor-plate to within 25 feet of the front of the anchorage, the cable itself emerging eight feet below the top of the masonry. In all previous wire bridges each cable was composed of seven strands. In this they contain 19, requiring 38 bars for their attachment. These bars are of iron, as preferable to steel for such a use. Investigations at the Pittsburgh and Niagara bridges have shown that the old style of preserving the chains is safe, viz: painting the chemically-cleaned surface of the iron and then imbedding the chain in hydraulic cement. The

rusting power of Brooklyn air is 20-fold that of Cincinnati. The main cables are not made on land and hauled across the river, but are laid up in place, the strands being first put 60 feet above the ultimate destination of the cable. Men called "regulators" are put upon ten cradles in the center of the main spans and in each of the land spans, to give the wires a uniform deflection as the cables are formed. All four cables are made simultaneously, and are put five or six feet above their destination to make allowance for all depressions. It will take about three years to make the main cables. It took nine months to lay 1,000,000 pounds of wire at Cincinnati. Preparations have been making for cable-laying for two years. As soon as the foot-bridge is completed all will be ready. Access will be had to the cradles of the regulators by this bridge, which will be 210 feet above the water. To protect such a frail structure against storms is no easy task, and Mr. Roebling predicts that the temporary works will be disabled more than once before the cables are finished. Inverted parabolic storm-cables serve to prevent the foot-bridge from being carried away bodily.

Irrigation of the Rhone Valley.

The inhabitation of the Rhone valley have, of late years, been remarkable sufferers from a variety of causes—the devastations wrought by phylloxera, the disease which has attacked the silk worms, and the necessity of giving up the cultivation of madder, which is no longer able to compete with artificial alizarine. It is known that a project was started a little time ago for making an irrigation canal from the Rhone. M. Dumont was charged to make the necessary studies and observations, and his scheme, as now matured, has been brought before the French Academy by M. Lesseps. The canal would begin above Condrien, and terminate in the outskirts of Montpellier, 61 meters above the sea level. The total cost is put at 110,000,000 francs. An irrigation zone would thus be formed in five departments, Drome, Vaucluse, Gard, Herault and Aube, with an irrigable surface capable of producing annually 450,000 tons of hay, and of supporting at least 100,000 head of large cattle more than at present. The canal could be easily applied in submersion of at least 80,000 hectares of vines on the plain, and thus afford an effective remedy against phylloxera. It would be complete in four years. M. Dumont considers that it need not be injurious to navigation, but that the present condition of the bed of the Rhone greatly needs improvement. It is desirable to obtain in the interior system of navigation a sufficient and uniform draft of water.—*Eng. Mechanic*.

A PROPOSED RAILROAD BUREAU.—Mr. Charles Francis Adams, Jr., in an open letter to Mr. Garfield, the representative of the Ashtabula district in Congress, recommends the establishment of a bureau of railroad statistics in connection with the Department of the Interior, the said bureau to consist of two officers, one an accountant and statistician, and the other a railroad expert and engineer. It should be the duty of the first to collect and put in shape for reference, information relative to the internal commerce of the country, and the second should investigate all railroad accidents, and especially such as present unusual features, or the causes of which are difficult of ascertainment. By this means the public would be made acquainted with such facts as the railroad companies are now under the strongest inducements to suppress. Apart from mere statistics, showing the number of accidents, the lives lost and injuries sustained, we should then know to what cause, whether carelessness, defective material, imperfect appliances, poor construction or natural agencies, each disaster was due. The experience of one road would then be made the experience of all, instead of limiting each official, as now, to his own narrow range of observation. The working of such an agency would also tend to enforce the adoption of the most improved appliances.

CANADIAN RAILWAY GAUGES.—The disadvantages attending the adoption of various railway gauges do not seem to be thoroughly appreciated in Canada. In the parliamentary returns of railways for 1875, we find a list of railways completed, in process of construction, or projected, which show no less than seven gauges. Their mileage, as given in detail, is as follows: five feet six inches, 606 miles; four feet eight and a half inches, 6,167 miles; three feet seven and a half inches, one and a half miles; three feet six and a half inches, one mile; three feet six inches, 819½ miles; three feet, 40 miles; two feet, eight and three-quarter inches, one and a half miles; total, 7,637 miles. There are still some permutations of the scale which might be used for future roads.

CANAL NAVIGATION.—The *Engineering News* says: A meeting of persons interested in canal navigation was held a few weeks since at Buffalo, to see what measures could be taken to improve the efficiency of these water-ways and to revive the traffic. The Belgian system of towing by cable on the bottom of the canal was strongly advocated, and additional steps were suggested for inaugurating such a system; but it was stated that there was already no legal hindrance to the introduction of the plan, and that whenever any one wished to introduce train boats they could do so. One party urged the laying of a T rail upon piles on the tow-path, and using small locomotives for traction.

Reduction of Miners' Wages.

Concerning the strike of the miners at Smartsville, Sucker Flat and Timbuctoo, the Grass Valley Union says:

We received a lengthy communication from Smartsville, on the subject of mining affairs connected with the strike of the miners of Smartsville, Timbuctoo and Sucker Flat. The communication is entirely too long to appear, in full, in our columns. We give some of the points sent to us by the miners of the places mentioned in the heading.

The wages of the miners having been reduced from three dollars to two dollars and fifty cents a day, per man, on the first of the present month most of the miners quit work. There was a parade with music and banners, and almost all the miners joined in a procession, thereby protesting against the reduction of wages. Our correspondents, the miners, go on and detail the oppressions which the companies, operating at Smartsville, Sucker Flat and Timbuctoo, have exercised towards the miners. The statement goes on to say that some eighteen months ago the Excelsior water company consolidated with John McAllis & Co., the later owning small claims and a flourishing general country store. After that consolidation the employees of the company were compelled to trade at the company's store, or to quit work. The company thus combined the mining business with a trade in ham, eggs, butter, etc. The miners were, by this order, compelled to pay from 30 to 35 per cent. more on their goods than they had previously to pay, when they were allowed to trade directly with Marysville, and at least 20 or 25 per cent. more than when they had the liberty of trading at any of the local stores. An instance is given in the article of coal oil. "Devoe's" brand of oil was sold at the Excelsior store for \$3.50 and \$3.75 per five gallon can, when it could be bought at another store, not two hundred yards distant, for \$1.75.

If a miner employed by the company was caught buying at the cheaper place he lost his situation. If one not employed by the company bought goods at the cheaper place the household supply of water was cut off—for the company supplies all water there used for domestic purposes. It is moreover asserted that single men employed there were expected to buy largely of fancy dry goods or have no work to do. Of course employed men, with families, had to patronize the dry goods department of that store in an extensive way. It is said that single men employed there have to board only at such houses as trade with the company's store. Formerly the companies had their own boarding houses, where each employee had to board and lodge, no matter where they ate and slept. It is also charged that an attempt was made to plant a "miners' physician" on the employees, and that the miners were to pay the doctor \$6 a year for each single miner, and \$12 for each miner with a family. This doctor was to have charge of the health of the miners and their families. An agreement to that effect was gotten up, but did not succeed in getting a sufficient number of signatures. In short, the miners, as they make out their case in the communication sent to us, are bulldozed in every way, so far as their food and clothing is concerned.

The Blue Point company, under the superintendence of Mr. Kemp, is excepted from the complaint of reduction of wages, and we infer also, from the tenor of the communication, that that company is not exercising the privilege of controlling the trade of employees.

The miners think that the companies operating in the district named could easily reduce expenses by cutting down the pay of some of the officers of the company who have little to do.

We gave a short statement of the contents of the miners' communication, and we believe we have covered the ground of the complaint. We express no opinion as to whether a strike will furnish a remedy in the matter. Strikes generally fail, and that too after damaging both parties in the contest. A man has a right to quit work when wages do not suit him, or for any other cause or reason; but when he does quit, he had better try to find some other place in which to labor, where he is better suited.

To quit and remain idle does not pay, and in this avaricious world appeals do but little good. We are strongly opposed to the reduction of miners' wages, and are still more opposed to systems which force working men to trade with particular mercantile establishments; yet we must say that we see no sure way to avoid such things or to right such great wrongs. Consolidations and monopolies are overshadowing the industries of the country, and their tendency is to reduce working men to mere serfs.

The other side of the question is thus given in the Nevada Transcript: We have mentioned the fact that the wages of miners for some of the companies on the Ridge, have been lowered 25 cents per day, and after the first of May the price will again be reduced 25 cents per day, making the wages then amount to \$2.50 per day. This is regarded as a hardship by miners, and is a thing we are sorry has happened. We have frequently expressed our opinions in reference to the matter, and have published such correspondence opposed to it as has been sent to us, and are still ready to do so. We always intend to be fair in any discussion affecting the interests of the county, and desire to give both sides of the question. With this view, we inquired the other day of one of the parties interested in the mining companies which have made the reduction, to learn that side of the question, and find the arguments to

be about as follows. In the first place, there are two parties interested in the question of wages. The capitalist desires a fair compensation for his labor and his money, as well as the laborer does for his work. The owners of the North Bloomfield mine have expended in the neighborhood of \$2,000,000 in the purchase of the ground and in opening it up ready for work. This amount, loaned at one per cent. per month interest, would amount to \$240,000 per annum. But supposing the amount is reduced from the above figure \$500,000—still the interest of the investment, alone, would amount to \$190,000 per year. This investment has been non-productive for a number of years. The largest yield of the mine so far, in any one year, was \$192,736, and that was in 1875-6. In 1874 it was only \$74,272. Hence it will be seen that the company have been paying \$3 a day per man for years, while the mine was unproductive, and while the interest of the investment alone greatly exceeded the gross yield of the property, to say nothing about the expense of working it. Of course it is expected the yield will be doubled or trebled in coming years, but the company feel entitled to a liberal return after investing such an amount of money and taking the chances of losing it all. The company further say that a majority of the work now done does not require skilled laborers, and that the price offered is better than is paid elsewhere in the State for the same kind of labor. They say that many of their men have been steadily employed for years. That ten hours make a day's work, while a farm hand has to work from 12 to 16. A laborer in the valleys gets from \$25 to \$40 per month and board. At \$2.50 per day, the wages amount to \$65 per month, for 26 days' work, and many men put in 30 days in a month. Board costs from \$5 to \$6 per week at boarding houses, and, if a miner cabins himself, he can live for about \$3 per week. In either case the company claims the wages at the reduced figure are a good deal better than other outside labor is paid, in any of the agricultural counties; while the hours per day are less, and the number of days working per month are three or four less than a farm hand has to work. This is the other side of the question, and we give it publicity so that the discussion may be fairly conducted.

The Bonanza.

Under the heading of "\$1,080,000," the Virginia Enterprise of the 8th says: This is the California mine dividend day. During the month its shipments have been over \$1,600,000, so there is no doubt about the dividend. We wonder if one in a thousand who reads the brief announcement every month on a certain day, that a certain mine has paid a dividend of \$1,080,000, has the slightest idea of what is necessary to be done in order to make such an announcement possible? Every one who ever owned a note in a bank knows that 30 days is a very brief period of time. To cause a mine to produce \$60,000 in a single day is a tremendous feat; to continue this product daily through weeks and months, almost without variation, is a marvel. It takes foresight, endurance, judgment and nice calculation, such as very few men possess in this world. The ore from which this mighty yield is extracted lies hid away almost a third of a mile below the earth's surface. It lies where consuming heat and baffling waters join their forces to try and drive away the invading miner. While the ore is being hoisted, every month 1,250,000 feet of lumber has to be lowered and put in position, to keep safe the weakening caused by the mighty excavations. While one level is being worked another has to be explored, for a drain of 500 tons of ore per day would soon level a mountain down. Then the Comstock is an uneasy fissure. In a single week, sometimes, the swell of the ground shivers into splinters 14-inch square timbers. Shafts and drifts and inclines and tracks have to be watched incessantly, for a mine, like a glacier, seems ever to be working. This is all below ground. Above the surface is a world of machinery, always to be kept in order—steam engines, air engines, cables, cages, air pipes, pumps and all the multiplied devices intended to expedite the work and lessen the dangers of mining. Five hundred men have to be lowered into and hoisted from the depths daily. Three hundred cords of wood have to be provided daily for fuel. And there must be no delays, no serious accidents. The needed repairs must be anticipated and provided for; the accidents must be anticipated and guarded against; the explorations must be carried on months in advance; the supplies must never fail. A vast space of forest-land, 30 miles away, has to be denuded of its timber yearly to fill the insatiable maw of this one mine. It requires 15,000,000 feet of timber and 100,000 cords of wood annually to supply the mine and to furnish fuel to hoist and reduce the ores. How many can appreciate the ability necessary to carry on this work without any mistakes? Many a man of mind sufficient to accomplish the feat would fail through sheer lack of physical strength. The work means being up at 5 o'clock in the morning; means two or three daily journeys into the depths, and when anything unusual happens, it means standing guard day and night, like a ship's captain in a storm, until the trouble is over. It means a mind large enough to take in the immense work going on at a glance, yet careful enough to include its smallest details and exact enough to anticipate the wants of the enterprise months in advance. For 10 months the California mine has monthly given up this tremendous yield.

Amador County Coal.

The *Ione City News*, in a description of "Carbondale" and its coal mines, says:

The Carbondale mine, under the supervision of J. F. Steinberger, Esq., has been opened evidently with a view to extensive working. Last Friday we made a visit to it and were most courteously received by the superintendent. Engineer Fleming turned the crank, and away we glided, at an angle of 30°, a distance of about 200 feet, which brought us to the entrance of the main tunnel. The tunnel extends for 150 feet in a north-north-west direction, and is being pushed through to the air shaft. The bed of coal is almost flat, is 10 feet thick and of very compact body. Borings which have been made proved beyond doubt that it extends, with but little variation in the depth from the surface, for several miles. The coal can be taken out very easily, at a small expense, and in immense quantities. Any number of men could be profitably employed in the mine, as there is an unlimited area of the coal available, and it can be worked straight-head without taking out with it any waste dirt or contiguous casing.

Those who have doubted the fuel properties of the Carbondale coal have done so mainly upon appearance, comparisons and unfair tests. Its brown-black, dull color when compared with the bright lustrous black of the imported article, will for a time detract from its ready sale. In the testing of it, it has been subjected to the same treatment that the anthracite and anthracite bituminous coal is; burned in the same grates and with the same draft—all of which is wrong, and an unfair test of this description of mineral coal. Of the three known varieties, the anthracite, bituminous and lignite, there is no question but the Carbondale deposits are of the latter variety. The texture of the wood from which it is formed is very distinctly traceable in it all. Occasionally pieces are found—which, perhaps from the peculiarity of their species, have resisted the mineral-forming process more than the great bulk of the buried forest, in which the woody nature remains almost *au naturel*. These may be whittled with a knife as easily as any piece of soft pine. That such carbonaceous matter will not make good fuel is too preposterous a proposition to need further reference to here. The combustible qualities of brown-coal, or wood-coal as it is called, are better understood in the Baltic States of Europe and the southeastern provinces of Australia, where it is in constant use for domestic fuel, steamboat, and all stationary bodies. Whether it is adapted to locomotives in California can only be surmised, as a great deal depends upon the shape and style of the furnaces. The day engineer, Mr. Fleming, at the Carbondale mine, finds no difficulty in running his engine with it, the only objection to it being, that it is now and again very wet—not very surprising, seeing he uses it quite green from the mine, which might do well enough if it were anthracite in place of lignite. He says "it doesn't blaze as much as Seattle nor as high;" this is conclusive that in its composition there is more carbon and less bitumen than in Seattle. The only precaution necessary to be taken in regard to Carbondale brown-coal is, that it be allowed a few days for the moisture which it contains to evaporate before sending it to market. It will then burn as brightly and give as much solid heat as the best qualities of Cumberland anthracite.

The bituminous clay, distributed in veins through the main body of the vein of coal, is a light colored clay, which, when dried, burns similar to sperm wax or pitch. The highly inflammable nature of this clay has attracted considerable surprise and comment. It was supposed by its appearance to be of no account, and was discarded as refuse. Last week, at the instance of Master Mechanic Stevens, of the Central Pacific railroad, who believes the clay is more valuable than any coal, a carload of it was sent to Sacramento. We have not heard how it proved itself. The light color of the clay where thoroughly dried closely resembles the pale yellow cast of hardened naphtha, as also does its specific gravity. Mr. Stevens, we are told, believes this clay will be specially valuable for making gas. Whether or not the coal is adapted for locomotives, or the clay for gas making, it is to be hoped—for the sake of providing a cheap fuel superior to wood, and less costly than any other fuel in the market available for domestic use by the working classes in the large labor centers of the State—that these bountiful resources will be speedily brought within the reach of consumers.

A RICH STRIKE.—The Rye Patchers are very much excited over a strike made in the Rye Patch. We have seen a specimen of the ore, and from the most reliable information attainable, that is, from the men who work in the mine, we learn that the body of ore, which is three feet wide, was struck on the 220-foot level in a drift run from the main shaft. Some choice specimens assay as high as \$3,000 in silver, and the whole three feet averages about \$800 per ton.—*Silver State*.

ADDITIONAL FORCE.—The Alps mine has added to the working force of the mine, so that there are now working in the mine alone 15 men, a large addition to what has heretofore been working. The mine is now shipping ore to the mill at the rate of six tons daily, preparatory to the mill starting to work. Outside of what is shipped by the mine, 400 tons are already on hand for the mill to start on.—*Pioche Record*.

USEFUL INFORMATION.

The Effect of Oil on the Sea.

A very interesting account of the application of oil to mitigate the raging of the sea, and to relieve a vessel in a storm, has been received by the Bombay mail, in relation to the *King Celtic*, a vessel of 1,490 tons, which left Liverpool in June last for Bombay. When off the Cape of Good Hope she encountered a heavy gale from the northwest, which continued for some time. Tremendous seas broke over the ship, bursting in the main hatch, washing away the hatch-houses and boats, smashing in the front of the cabin, and destroying the Captain's and officers' stores and clothing. A young lad, one of the crew, was carried overboard, and it was impossible to rescue him. The gale lasted for nearly five days, and though the vessel stood it very well, it was impossible to repair any of the damage, as the waves were continually sweeping her decks. At length the chief officer, Mr. Boyer, suggested the trial of throwing oil upon the water. Two canvas clothes-bags were obtained, and into each two gallons of fine oil were poured, the bags being punctured slightly, and hung over each quarter in tow of the vessel. The effect was magical; the waves no longer broke over the poop and sides of the ship; but several yards away, where the oil had spread itself over the surface, and around the poop, in the wake of the vessel, was a large circle of calm water. The crew were thus able to repair the damage with greater ease, and the ship was relieved from the tremendous shocks she had previously received from the heavy seas. The bags lasted two days, after which, the worst fury of the gale having expended itself, no more oil was used.

RAPID SYSTEM OF PLASTERING.—By the use of this system, the lathing and two coats of plastering, with lime and hair, give place to large slabs fixed to the joists, which form the body of the ceiling at once. The edges of these slabs are bevelled reverse ways, and fit into each other so that the stopping cannot be shaken out. The faces of the slabs are made rough, and the whole receives a thin finishing coat of cement or stucco, which effectually conceals the joints, and produces ceilings of good appearance. By this means no time is lost in waiting for drying; and the annoyance of dirt and rubbish caused by mixing and using lime and hair is entirely avoided. The manufacture of the slabs may be briefly described. A sufficient quantity of plaster and fiber is mixed with glue-water; half of this, while in a plastic state, is spread evenly upon a plate-glass bench, with edges raised three-eighths of an inch, beveled. A sheet of strong open canvas is then stretched tight across, and wrapped round two laths which are embedded in the two edges of the slab. The object of having these laths is to tighten the canvas, and to stiffen the edges of the slabs in their span from joist to joist. The remaining portion of the plaster and fiber is spread evenly upon the canvas, which then remains firmly embedded through the center of the slab. A bass broom is then passed over the face of the slabs to form a "key" for a finishing coat. When sufficiently set, the slabs are removed from the bench, and exposed to the air to dry. These slabs are two feet six inches wide, of sufficient length to reach across four joists, and are secured to the joists by driving 1½ in. zinc nails through the laths before mentioned, and about four inches apart, along wherever the joists come. The joints are then roughly stopped with cement, and the whole receives a thin "setting" or finishing coat of cement or "stucco," as in the ordinary way. The system certainly has its advantages.—*Builder*.

TEST PAPER FOR WINES.—*Les Mondes* says that *enokrine* is the name of a test-paper sold in Paris, for the purpose of detecting the fraudulent coloration of wines. With a genuine red wine the color produced is a grayish-blue, which becomes lead-colored on drying. With magenta and other aniline colors, it turns a carmine red; with ammoniacal cochineal, a pale violet; with elderberries, the petals of roses, etc.; a green; with logwood and Brazil wood, the color of dregs of wine; with Pernambuco wood and phytochrome, a dirty yellow; with extract of indigo, a deep blue. The manipulation required is very simple. A slip of the paper is steeped in pure wine for about five seconds, briskly shaken in order to remove the excess of liquid, and then placed on a sheet of white paper to serve as a standard. A second slip of test-paper is then steeped in the suspected wine in the same manner and laid beside the former. It is asserted that 1-100,000th of magenta is sufficient to give the paper a violet shade, whilst a larger quantity produces a carmine red. The inventors of the test paper, MM. Lainville and Roy, are also said to have discovered a method of removing magenta from wines without injuring their quality, a fact of some importance, if it be true that several hundred thousand hectoliters of wine sophisticated with magenta are in the hands of merchants.

CEMENT FOR JOINING AMBER.—A solution of hard copal in pure ether, of the consistency of castor oil, is suggested by Ph. Rust for cementing amber. The carefully-cleaned surfaces of fracture, coated with the solution, should be pressed together, and retained in contact by

means of a string wound around the object, or in some other suitable way. The operation should be performed as rapidly as possible, since the evaporation of the ether impairs the adhesiveness of the cement; so that all arrangements for compressing the object should be made before laying on the cement. A few days are required for the complete hardening of it. In repairing tubes, as for pipes, any of the solution happening to pass into the interior should be carefully removed at once with a slender feather.

CLEANING SILK.—The following mode of cleaning silk garments, says the *Manufacturers' Review*, has been successfully tested. The garment must first be ripped and dusted. Have a large flat board; over it spread an old sheet. Take half a cup of ox gall, half a cup ammonia and half a pint tepid soft water. Sponge the silk with this on both sides, especially the soiled spots. Having finished sponging, roll it round on a stick like a broom handle, being careful not to have any wrinkles. Silk thus washed and thoroughly dried, needs no ironing and has a luster like new silk. Not only silk, but merino, barege or any woolen goods may be thus treated with the best results.

MECHANICAL POWER OF WATER.—Water is a purifier, a cleanser, a dissolver and a mechanical power, and will run along down an incline the solid ingredients of town sewage, with road detritus—such as grit and silt—the moving power of water being in proportion to the volume, the vertical depth and the gradient down which the flow is directed. Flushing by volume and head, artificially formed, will remove detritus from sewers of low gradients, where accumulation may have taken place. A velocity in the sewage of two feet six inches per second will remove any solids likely to be passed into drains and sewers.

GOOD HEALTH.

Remedy for Rheumatism.

EDITORS PRESS:—To know the special causes of disease and to remove them is generally all that is needed to preserve health, if done in time. Rheumatism is no exception to the rule. Although regarded as a hereditary disease, persons subject to it need favorable conditions to develop it. Dr. Hall says, that persons may bring it on by riding in a top buggy with the sides open, so as to get a current of air against the shoulder.

Four or five years ago I had a severe attack of rheumatism for the first time, though my father was subject to it, and his father was also. I took it in my hands and wrists by exposure about water, and thinking that it was the result simply of heavy lifting of fruit chests during the previous summer, I poured cold water on the hands and wrists to strengthen them. But they got worse instead of better, when I found I had the rheumatism. When I reflected that my Chinamen are not subject to this affliction, although exposed to cold fogs during a portion of the berry-picking season, and when I remembered that they practiced bathing their arms and legs with hot water, I thought I had "struck a lead." So I used hot or warm water whenever I washed my hands, keeping the feet dry and the whole system comfortable by a change of clothing to suit the weather, and I soon cured myself. I am still careful in these habits, avoiding exposure to cold or wet, and applying the warm water still whenever I think it necessary, and although I have now and then threats of an attack, I keep it at arm's length. Santa Clara, Feb., 1877. I. A. W.

POISONS.—For any poison, the most speedy, certain and most frequently efficacious remedy in the world, if immediately taken, is a heaping teaspoonful of ground mustard, stirred rapidly in a glass of cold water, and drank down at a draft, causing instantaneous vomiting. As soon as the vomiting ceases, swallow two tablespoonfuls or more of sweet-oil, or any other mild oil. If no ground mustard is at hand, drink a teaspoonful or more of sweet-oil or any other pure mild oil, melted hog's lard, melted butter, train oil, cod-liver oil, any of which protect the coats of the stomach from the disorganizing effects of the poison; and, to a certain extent, by filling up the pores of the stomach (the mouths of the absorbents) prevent the poison being taken up in the circulation of the blood. Persons bitten by rattlesnakes have drank oil freely and recovered. These are things to be done while a physician is being sent for.

EXTRACTION OF A LIVING INSECT FROM THE EAR.—The *Archives Medicales Belges* relates the following case: A little girl, three years old, put an insect, "*bete du bon Dieu*," into her ear. Sharp cries, agitation and convulsive symptoms ensued. Injections of water were made without result. The physician then conceived the idea of asphyxiating the insect by means of chloroform; he dropped four drops of chloroform upon a small piece of cotton, which he introduced into the ear. Immediately the child ceased crying and complained no further of any disagreeable sensation; the insect had become asphyxiated; an injection of warm water brought it away dead, and no further trouble ensued.

Out-Door Safety.

The fear of the weather has sent multitudes to the grave, who otherwise might have lived in health many years longer. The fierce north wind and the furious snow storm kill comparatively few, while hot winter rooms and crisp summer suns have countless hecatombs of human victims to attest their power. Except in localities where malignant miasms prevail, and that only in warm weather, out-door life is the healthiest and happiest, from the tropics to the poles.

The general fact speaks for itself, that persons who are out of doors most take cold least. In some parts of our country, near one-half of the adult deaths are from diseases of the air passages. These ailments arise from taking cold in some way or another; and surely the reader will take some interest in a subject, which, by at least one chance out of four, his own life may be lost.

All colds arise from one of two causes.

1. By getting cool too quick after exercise, either as to the whole body, or any part of it.

2. By being chilled, and remaining so for a long time, from want of exercise.

To avoid colds from the former, we have only to go to a fire the moment the exercises cease in the winter. If in summer, repair at once to a closed room, and there remain with the same clothing on, until cooled off.

To avoid colds from the latter cause, and these engender the most speedily fatal diseases, such as pleurisy, croup, and inflammation of the lungs, called pneumonias, we have only to compel ourselves to walk with sufficient vigor to keep off a feeling of chilliness. Attention to a precept contained in less than a dozen words, would add 20 years to the average of civilized life: keep away chilliness by exercise; cool off slowly. Then you will never take cold in-door or out!—*Hall's Journal of Health*.

BEEF-TEA.—Dr. Christian says that "every one will be struck with the readiness with which certain classes of patients will often take diluted meat-juice and beef-tea repeatedly, when they refuse all other kinds of food." This is particularly remarkable in "cases of gastric fever, in which," he says, "little or nothing else besides beef-tea or diluted meat-juice" has been taken for weeks or even months, "and yet a pint of beef-tea contains scarcely one-fourth of an ounce of anything but water." The result is so striking that he asks, "What is its mode of action? Not simply nutritive; one-fourth of an ounce of the most nutritive material cannot nearly replace the daily wear and tear of the tissues in any circumstances. Possibly," he says, "it belongs to a new denomination of remedies." It has been observed that a small quantity of beef-tea, added to other articles of nutrition, augments their power out of all proportion to the additional amount of solid matter. The reason why jelly should be in nutritious and beef-tea nutritious to the sick is a secret yet undiscovered, but it clearly shows that careful observation of the sick is the only clue to the best dietary.

COFFEE AS AN INVIGORATOR.—A correspondent of the London *Lancet*, who owns a water-power mill, says: "I am frequently compelled, at this season of the year, to have men working in water even in frosty weather. I find the following allowance gives great satisfaction to the men, and we never have a case of cold or injury to the men in any way: Kettle of coffee, made with half sweet milk, half water, three or four eggs, whipped, poured into it when off the boil; hot toasted bread with plenty of butter of finest quality. Serve up this every two and a half hours. The expense is much less than the usual allowance of whisky, and the men work far better, and if care is taken to have the coffee, milk (cream is still better), bread and butter, and especially the butter, of the very finest quality, the men are delighted with it. I am persuaded it would be worth while to try this allowance instead of grog. Giving extra grog gives the men a notion that it is good for them, and perpetuates the belief in stimulants among workmen."

WORTH KNOWING.—We are assured that one pound of green copperas, dissolved in one quart of water and poured down a water-closet, will effectually concentrate and destroy the foulest smells. On board ships and steamboats, about hotels and other public places, there is nothing so nice to purify the air. Simple green copperas, dissolved in anything under the bed, will render a hospital, or other place for the sick, free from unpleasant smells. In fish-markets, slaughter houses, sinks and wherever there are offensive gases, dissolve copperas and sprinkle it about, and in a few days the smell will pass away. If a cat, rat or mouse dies about the house and sends forth an offensive gas, place some dissolved copperas in an open vessel near the place where the nuisance is, and it will purify the atmosphere.

A BEAUTIFUL COMPLIMENT TO THE PHYSICIAN.

—I dare not place any gift, however beautiful, or any success, however brilliant, above the talent or the skill which can relieve a single pang, and the self-devotion which lays them at the feet of the humblest fellow creature.—*Oliver Wendell Holmes*.

MINING SCIENTIFIC PRESS

W. B. EWER, SENIOR EDITOR.

DEWEY & CO., Publishers,

A. T. DEWEY, GEO. H. STRONG,
W. B. EWER, JNO. L. BOONE.

Office, No. 224 Sansome Street, S. E. Corner of California Street, San Francisco.

ADVERTISING RATES.	1 week.	1 month.	3 mos.	12 mos.
Per line.....	.25	.80	\$ 2.00	\$ 5.00
Half inch (1 square).	\$1.00	\$3.00	7.50	24.00
One inch.....	1.50	4.00	12.00	40.00

Four weeks are rated as one month. Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing in extraordinary type or in particular parts of the paper inserted at special rates.

SUBSCRIPTION IN ADVANCE.—Postage paid—one year, \$4; six months, \$2.25; three months, \$1.25. Remittances by registered letters or P. O. orders at our risk.

Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing in extraordinary type or in particular parts of the paper, inserted at special rates.

Four weeks are rated a month.

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription.

THE ORIGINAL ARTICLES in this paper are mostly set in solid type, giving in our columns one-third more reading than is contained in ordinary leaded matter.

ADDRESS all letters to the firm, and not to individual members, or others, who may at any time be absent.

Our latest forms go to press on Thursday evening.

SAN FRANCISCO:

Saturday Morning, Feb. 24, 1877.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Hoe's Printing Press; Home Industries—The Pacific Chain Works, 113. Premiums for the Mechanics' Fair; Water for Mining; Comstock Papers—No. 17, 120. Washington's Birthday; Action of Air Currents; New Leveling Target, 121. Patents and Inventions; Notices of Recent Patents; Testing Roasted Silver Ores; Academy of Sciences, 124. An Elevated Railroad for San Francisco, 125. ILLUSTRATIONS.—The New Hoe Printing Press, 113. Leveling Target, Adopted by the U. S. Coast Survey; The Philosophy of Air Currents, 121.

CORRESPONDENCE.—Mining vs. Speculative Robbery; Quartz Interests of Amador, 114.

MECHANICAL PROGRESS.—Friction and Wear of Bearings; Demagnetizing Tools; Magnetizing Wheels; Steel Experiments in Russia; New Aerial Machine; Fluid Compressed Steel; Phosphor Bronze Winding Rope; A Tube Street, 115.

SCIENTIFIC PROGRESS.—Experiments with the Telephone; A Talking Machine; Hydraulics of the Ancients; Late Theories on the Earth's State; Pocket Microscope; An Apt Comparison, 115.

MINING STOCK MARKET.—Sales at the San Francisco, Pacific and California Stock Boards; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 116.

MINING SUMMARY from the counties in California, Nevada, Arizona, Idaho and Utah, 117-24.

THE ENGINEER.—Government Tests of Iron and Steel; The East River Bridge; Irrigation of the Rhone Valley; A Proposed Railroad Bureau; Canadian Railway Gauges; Canal Navigation, 118.

USEFUL INFORMATION.—The Effect of Oil on the Sea; Rapid System of Plastering; Test Paper for Wines; Cement for Joining Amber; Cleaning Silk; Mechanical Power of Water, 119.

GOOD HEALTH.—Remedy for Rheumatism; Pains; Extraction of a Living Insect from the Ear; Outdoor Safety; Beef-Tea; Coffee as an Invigorator; Worth Knowing; A Beautiful Compliment to the Physician, 119.

GENERAL NEWS ITEMS on page 125 and other pages.

MISCELLANEOUS.—Nest-Building Extraordinary; The Lady Bryan Machinery; Mount Hamilton, 114. Reduction of Miners' Wages; The Bonanza, 118. Amador County Coal; A Rich Strike; Additional Force, 119. Our Lead Product; The Mendocino Gold Mines; The Outlook in Eureka District; The Leaching Process; An Important Discovery, 122.

NEW ADVERTISEMENTS.

Tulloch's Automatic Ore Feeder, F. Ogden, S. F.; Pacific Iron Works, Rankin, Brayton & Co., S. F.

DELAY OF CENTENNIAL AWARDS.—The *Herald's* Philadelphia special says: Although nearly five months have elapsed since the official announcement of awards to exhibitors at the Centennial exhibition, and over three months have passed since closing, not a single exhibitor has yet received either a diploma or a medal, and but very few have been favored even with reports from their exhibits. This causes general dissatisfaction, the fault being at the Centennial Commissioners' office, where the reports are delayed. In answer to the question when the reports upon exhibits would be ready, the inquirer was told they were all ready; but when, seeing a pile of them upon a table, he asked if the reports had all been sent out, he was answered, "oh we are holding them back to send diplomas with them." As to when the diplomas would be likely to be sent out, the Director General's Secretary stated that those awarded to foreign exhibitors had been transmitted, and they were going to begin on American diplomas in about a month. As to how long it would take to get through the business, he would not say.

The Southern Pacific railroad is now completed to a point 37 2-10 miles east of Indian Wells. The work has been pushed forward with great energy.

Premiums for the Mechanics' Fair.

As we have previously mentioned, the 12th industrial exhibition of the Mechanics' Institute will open to the public on Tuesday, August 7th, and continue from 10 A. M. to 10 P. M., for one month thereafter. The pavilion will be opened for the reception of goods from and after Monday, July 16th. The driving engine will be in operation one week previous to the opening and exhibitors of machinery in motion will be required to have their machines in running order on that day. No charge of any kind will be made to exhibitors for space. Steam and water will also be furnished free, in reasonable quantities.

The premium list has been issued by the officers of the exhibition. It is important to remember that all premiums will be for the first order of merit only. No second class awards or decisions will be made or reported in any case, unless otherwise specified in the premium list. No premiums will be awarded to sewing machines, in accordance with the request of agents. In the list of paintings, outside of the regular medals for certain classes of work, a prize of \$250 will be given for the best painting in oil by a local artist, and a similar prize for the largest and best display of paintings by any exhibitor.

By the means adopted, each article in the premium list must stand on its own merits. It will be understood that while one class may be considered inferior in merits to another class, yet the awards made will be for the best (as particularly specified) in that class to which the article receiving the award belongs. A copy of the award of the jury, certified to by the proper officers, will, in all cases, be given when demanded, for which no fee will be charged. The management state elaborate experimental tests will be made whenever practicable, and the results embodied in a formal report. In cases where cash constitutes the premium, as in the horticultural department for instance, the awards vary in accordance with the value of the exhibit, and the list already published may be elaborated if thought advisable by the Board. The managers do not consider the list already issued as complete, nor are those articles subject to premiums limited to those enumerated. One of these premium lists will be forwarded to any one desiring it, by addressing the Secretary of the exhibition, 27 Post street.

Water for Mining.

Although the rain which has fallen thus far this season has been plenty for the purposes of the farmers thus far, the fall of snow in many parts of the mountains of the State has been so light that the water in the mining ditches is already falling. In fact, unless we have a few more good storms next month, many mining camps will suffer. The rains thus far have been so warm that in place of leaving snow on the high mountains they have melted what there was there. Of course with no snow to keep the streams running the miners must stop work.

The miners naturally took advantage of what water there was running in the ditches during and after the storms, and they used it to the best advantage, too. The rains were so long delayed that the miners had plenty of time to get their claims in first-class order for work, so that when the water came they "turned it loose" with great effect.

The miners draw their supplies of water from high up in the mountains, where nature stores it up in reservoirs of snow. Long and expensive ditches bring it to the claims where it is to be used, and on the abundance of the supply depends almost entirely the result of the year's work for the gravel miner. Of course, if snow is scarce, water will be scarce also, so that the miner looks to the snow for financial salvation as the farmer looks to rain for his.

As we have stated, thus far the deposits of snow in the mountains are very light for this season of the year. Heavy snows from this out for the next month or more, will help the miners out. If they do not come, in a good many camps the prospects for a good season's work are poor, for a warm rain or two, or a few days' sunshine, will melt what little snow remains, and then the ditches will run dry. The gravel miners are anxiously awaiting for the next storm, and we hope it will not be long in coming.

BULLION SHIPMENTS.—Since our last issue shipments of bullion from prominent mines have been as follows: Con. Virginia, 17th, 6 bars, value, \$19,636.42—February to date, \$167,076.79; California, 17th, 33 bars bullion, value, \$132,726.47—total to date, \$519,349.99; Washington, (Cal.), 561 ounces; Gila, 10th, \$2,341; Tybo Con., February 13th, \$15,319.09—total to date, \$23,837.13; Leopard, February 19th, \$5,200; Modoc, 18th, \$5,250—total to date, \$15,840; Manhattan, 20th, \$12,400.

The resident physician at the small-pox hospital reports to Mr. Gibbs, chairman of the hospital committee of the Board of Supervisors, that during the week ending last Saturday night 25 patients were received, four were discharged cured, and seven deaths occurred. The total number of patients under treatment was 67.

Comstock Papers.—No. 17.

The Big Mills of Washoe.—They Adhere to the Old Methods.

Notwithstanding the success of amalgamation by the pan or Washoe process had been fully established by the experimental trials made in the summer of 1860, as already related, such was the distrust of the new plan entertained by the Ophir, Gould & Curry and other of the leading companies on the Comstock, that they, acting under the advice of the old school of metallurgists, declined to adopt it in the extensive reduction works commenced by them in the fall of 1860 and finished the following year. Another reason for these companies sticking to the old and more expensive methods was the belief entertained by them that the great body of their ores was much richer than they afterwards proved to be; it having been supposed that an expense of \$40 or \$50 per ton for their reduction could well be borne, provided the work were so effectually done as to secure a very high percentage of the gold and silver they contained. How much these companies overrated the value of their ores at the start may be inferred from the fact that they offered, in the spring of 1860, to contract with Judge Walsh for the reduction of large quantities thereof at an average rate of \$75 per ton, it not being their intention then to work anything of less value than this. Acting under these misapprehensions these parties projected their reduction works on an extensive and costly scale, these establishments in the subdivision of their departments, the elaboration of the ores, and, in short, in both completeness and details, conforming largely to European models.

The Mill of the Ophir Company

Was put up in Washoe valley at a point 12 miles westerly from their mine, this site having been selected because of its proximity to wood and water and in the expectation that a railroad would soon be built between these two points. The buildings erected here covered an area of fully an acre, everything having been constructed on a grand scale. Besides the main edifice, an immense building was put up for the use of the patio process, which was here employed for a time on the poorer class of ores. Shops, stables, carriage houses, quarters for workmen, superintendent's residence, offices, etc., were all well built and capacious. The machinery, material and workmanship were also first class, the cost of the entire hacienda having amounted to over \$1,000,000. Besides the crushing mill, carrying 36 stamps, several furnaces for roasting or chloridizing the ores were provided, the Freiberg in connection with the patio process having been here practiced. Rows of huge barrels, used for amalgamating purposes and extending the whole length of the mill, were kept in ceaseless revolution. The services of 100 men were constantly required in the several departments, besides nearly as many more in cutting and hauling wood, making lumber, burning charcoal and other outside employments apart from those connected with the mines. A hundred tons of ore were worked here daily, independent of that disposed of by the patio method. In addition to the ground about their works the company owned 700 acres of grazing and agricultural lands lying in the valley near by and 9,000 acres of woodland on the adjacent mountains, where a saw-mill had been put up for cutting their own lumber. Over this grand establishment Captain William L. Dall exercised a general supervision, with Captain Henry A. Cheever for his assistant, both of these men having had a long and honorable service as commanders in our merchant marine.

The Ores Grow Poorer and the Works Cease to Run.

Thus situated, the owners of the richest section of the Comstock lode, and having within themselves everything requisite to work their ores to the best advantage, it was expected by everybody that the Ophir company was on the highway to sure and early fortune, and for a time their affairs really seemed prosperous enough. But their ores, which at first averaged about \$150 per ton, soon began to decline in value, leaving, under their expensive modes of manipulation, such a narrow margin for profit that they were obliged to supplant the same by the more cheap and simple but much derided Washoe pans, through the use of which they would no doubt have reached satisfactory results had not their works been located at such a great distance from their mine and had not the latter within a short time after this substitution been pretty well exhausted of its paying ores. As it was, this company, with all their bright prospects at the start, their valuable mine, extensive works and great facilities for ore reduction, achieved but a brief and moderate success; their expenses after two or three years having outgrown their income to such an extent that they found it expedient to close up their works, which, after their own ore supplies had failed, could not, owing to their remoteness, compete for custom work successfully with mills located nearer the mines.

The Final Collapse.

Having ceased operations and stood idle for a

time, the business of dismantling this vast establishment was at length commenced, some of the machinery and more valuable material being disposed of to one party and some to another, until its entire demolition was finally accomplished, the company having meantime disposed of most of their other property in the neighborhood. With the stoppage of the reduction works the considerable town built up around them was depopulated and speedily went to decay, scarcely a house being now left in the once flourishing city of Ophir to mark where it stood. The extinction of the town and of everything pertaining to it has been as utter as of the once promising industry which built it up.

The Gould & Curry Mill,

Which was commenced about the same time and finished a little later than the Ophir works, surpassed the latter not only in size and cost of construction but also in style and perfection of finish. Possessing a property of great supposed value, the owners of this mine, the most of whom were men of wealth and liberal notions, determined that they would put up an establishment commensurate with the magnitude and importance of their mine and which should out-rival anything of the kind ever before constructed in this or any other country, a purpose in which they were heartily and ably seconded by their general Superintendent, Charles L. Strong, also a man of large ideas, and by no means deficient in enterprise, energy and practical ability. With such a management, well supplied with money, the grand undertaking after being entered upon was pushed ahead rapidly, the site fixed for their structure having been a small flat at the junction of Six and Seven Mile canyons, two miles northeasterly of Virginia City. The spot was a rugged one, rocky and uneven, the cost of clearing away the ground and preparing for the foundation of the main building having amounted to more than had yet been expended upon any mill in the Territory. The massive walls laid for the reception of the main edifice, which was 250 feet long with wings 75 feet in length, all built of timber, were constructed of hewn stone, taken from a quarry near by, and dressed at great expense. The engine, of 150-horse power, a splendid piece of machinery, was built at the Pacific works, in San Francisco. There were eight batteries of five stamps each, capable of crushing 40 tons of ore per day. For generating steam to propel this engine, six furnaces, with three boilers, each 26 feet long and 42 inches in diameter, with 14-inch flues, were provided. In the various departments of this establishment, notwithstanding every labor-saving device then known in the business had been introduced, the services of 75 men were required, working in relays day and night, operations here never having been interrupted. With its terraced walls and numerous out-buildings, the place bore something the appearance of a fortified city.

And the End.

This company, like the Ophir, entertaining at first a great distrust of the Paul or pan process, employed at the outset the Tyler or Veatch plan of amalgamation, which involved the use of numerous deep tubs, the system being a mixture of the German, the patio and the pan process, which latter was after a time wholly adopted. The total cost of the Gould & Curry mill, all accessories and surroundings included, amounted to over \$1,250,000, a good deal of this expenditure having been of a kind that would, with our present experience in the business of ore reduction, be considered superfluous, and some of which was even at that time by many believed unnecessary. The history of this grand and costly establishment was so similar to that of the Ophir that we need not here rehearse it in detail. After a successful career extending through a few years, the current expenses began to drag heavily on the company and the mine itself giving out, brought operations at last to a stand-still, after which the work of disintegration began and proceeding at rapid pace, has left only the massive foundations of the great mill to attest where it stood.

MINES IN THE BASE RANGE.—The result of the present great mining trial is of peculiar interest to our citizens and readers, and of great importance to mine owners in this district. The Base range has been troubled and vexed with a multiplicity of theories bearing on the geology of the country and the deposition of mineral bearing veins, and outside capital has always been very timid in investing in limestone formations ever since the subsidence of the White Pine excitement; yet the rewards for continued explorations have been just as certain, and the returns equal in value, as any other mining section on the Pacific coast, not even excepting the Comstock. This has been peculiarly the case in the Eureka district, and the developments in depth have been of a character that has astonished the early doubters. Call them what you may—pipe, segregated, fissure, or contact veins, walls, or no walls—and the fact remains that at a depth of 1,000 feet ore is found as rich and valuable as at the croppings or surface, and with every indication of a permanent character at a lower depth. We do not propose to comment on either of the rival theories now being ventilated, for decisions of the courts will not alter geological formations, but to call attention to the immense ore bodies that do exist from the surface to an unknown depth, and we think we can predicate from that fact the continued prosperity of Eureka.—*Sentinel*.

Washington's Birthday.

As we write it is the eve of another anniversary of the birth of Washington. Time has brought us 145 years from his birth, and yet his name and memory stand where they have stood for a rounded century—first in the hearts of his countrymen. Later years have brought us newer heroes. Other names have been placed beside his in the country's roll of honor, but they do not detract from the glory of him whose patriotism and virtue they have emulated. Rather do they show us that his example has been of force with his people and that his life and work were not in vain.

Did the reader ever contemplate the advantage which we, as a people, have in the memory of Washington? Other nations have their heroes, but none so real, so genuine, so true as he. It has been the tendency of modern investigation to discover signs of unreality in the personages which many nations hold in high esteem. The Swiss have been well nigh robbed of their William Tell. He has been pronounced a myth. The tragic apple, which caught the winged shaft ere its fellow could seek the tyrant's heart, has been declared apocryphal. It has passed through the press of investigation and has run out in the cinder of distrust. Not so with Washington. He was a real and tangible man, for we have his clothes in the Patent Office at Washington. The demon of investigation has done its best to dull the edge of the hatchet which has cut its way down through a hundred and forty years of history and is as keen to-day as when it first scored the shins of the paternal tree. All honor to our Washington. All honor to the hatchet which cuts the fingers of those who would tear it from its place in the national heart.

The thought of Washington is a profitable theme for the American people to contemplate at this time. Never since his birth has his anniversary found his people in such a situation politically as now excites us. There have been trying times when war threatened and afterwards when its dire presence cursed the country. The situation to-day is different and, as we regard it, teaches us a lesson of thankfulness for our national holiday. What trying issues have come before the American people during the last two months! What opportunities for hot-headed counsels and hot-handed deeds. The whole political complexion of the country has been hanging upon the thread of doubt since the election day in November last. It has been impossible to tell which way the scale would turn. What other country in the world would have stood in dignified silence until the supreme law should dissolve the doubt? How many nations could have restrained the arm of tumult and turmoil during such a season of suspense? What people could have so nobly curbed the power of passion or prejudice until peaceful processes should declare the result?

It seems to us that the American people has reason to be proud of itself for this its latest achievement. It is a noble attribute to exhibit for the beginning of its second century of national life. It is a most promising surety of its future. It is such an offering as this which the country makes to commemorate a birthday of Washington. It is easy to believe that the calm earnestness and charity of purpose which have been shown in the national behavior during this our latest trial is a fitting reproduction of the spirit which led to victory under Washington. The times called for different manifestations but the spirit was the same. It was a spirit of belief in our institutions and of trust in the idea of popular government. It is true that factionists on either side have made angry threats, but they have found no answering approval in the national heart. That heart has been true and calm, approving the reign of law and order, content to abide such result as ordained methods shall set forth.

In the face of such an experience we rejoice again in the memory of Washington. We recall his quiet dignity, his unflinching patriotism, his unswerving devotion to the best good of the whole country. We honor him again for his lofty example. We look forward confidently to the unnumbered years during which his spirit shall still guide us, and we trust that in each of those years the American people may see in its growth, in its peaceful prosperity, in its noble and self-sacrificing love of country, some fresh evidence that the founder of the republic builded well. No better monument to Washington can be reared than that in which all of us can build a part, and that is the future of our beloved land.

NOVEL MINING CONTRIVANCE.—The Lyon County *Times* has the following: Mr. Wyman, who is placer mining in the gulch just east of town, has lately had in operation a new contrivance, so far our somewhat extended observation goes. The water and gravel from his sluices falls into a box, in which a horizontal shaft with projecting arms is made to revolve by a belt extending to a water-wheel a convenient distance away. The box is shaped to closely fit the revolving arms; is made watertight and serves to retain everything passing from the sluices until thoroughly washed, and also to catch all of value which escapes from the riffles above.

THE assessments of the mines of the coast for the month of February are 24 in number, as follows: Nevada, \$873,500; California, \$62,050; Arizona, \$15,000. Total amount, \$950,550.

Action of Air Currents.

The accompanying engravings illustrate in a comprehensive manner an interesting study into the wonders which are wrapped up in air currents. Often in our going about over the face of the earth we are struck with the peculiar behavior of the air currents when they meet obstructions, natural or artificial. Some points in their actions may be better understood after reading the following.

Visitors at the Centennial remember the wonder which they felt at seeing balls suspended in the air without any visible means of support.

The Phenomenon.

In exhibiting the Westinghouse air brake, in

in the direction shown by the arrow, but sometimes it remains stationary, owing to the fact that the center of gravity not coinciding with the geometrical center; for the same ball, once made to rotate by an external force, will continue the rotation with increased speed. The vertical inclination of the jet may be changed to about 45° before the ball loses its state of suspension and drops off.

A similar phenomenon, a ball dancing on top of the water jet of a fountain, is often seen, and will likewise remain sustained if the jet is more or less inclined.

The Explanation.

The investigation of the cause of this phenomenon was commenced by Mr. H. Bilgram with an examination of the course the air current takes in striking the ball. This investigation

LEVELING TARGET ADOPTED BY U. S. COAST SURVEY.

machinery hall, a receiver filled with compressed air, at about 70 pounds pressure to the square inch, is required. When the brake is not shown in operation the air of the receiver, being continually supplied by an air pump, is allowed to escape through a nozzle of about one-eighth-inch bore, set to a vertical inclination of about 30°. Over this jet of air is placed a ball

revealed the fact that the current $a\ b$ (Fig. 2), instead of leaving the ball in the line $b\ c$, as might be expected, follows the curvature of the ball along the line $b\ d$, and at length leaves the ball in the line $d\ e$. A light ball, when placed in the jet, is struck nearly centrally (see Fig. 3); the current envelops the whole ball and unites again, leaving the ball in the line $d\ e$, appearing

THE PHILOSOPHY OF AIR CURRENTS.

(see Fig. 1), which remains afloat in the air without any visible means of suspension. There are five balls; a solid glass ball of one and one-half inches diameter, two solid wooden balls of three inches and three and three-fourth inches diameter, and two hollow rubber balls of three inches and five inches diameter, each of which, when placed in the jet, will show this phenomenon. Even more curious it appears when two balls are suspended simultaneously; the current of air, after leaving the small glass ball, being sufficiently strong to give support to the largest of the rubber balls. The impression this experiment creates is very striking indeed. As a rule, the suspended ball rotates very rapidly.

as though the current was passing through the ball. It can, however, easily be found that the upper branch of the current is stronger than the lower one.

By a series of subsequent experiments, it was found that any current of air striking a convex surface has the tendency to follow that surface. One of these experiments is as follows: Attach to one end of a small tube, about one-eighth-inch to one-fourth-inch diameter, and four inches to six inches long (which may be made by rolling up a piece of writing paper), a piece of thread or yarn, about four inches to five inches long. Blow through the other end of this tube and direct the current against an ob-

ject with a convex surface. The thread, following the current, will indicate a deflection, as shown by Fig. 4.

After demonstrating this fact, the next step was to find its cause. It is well known that any current tends to carry along with it the surrounding particles of air; hence, the supposed current $b c$ (Fig. 2), being freely supplied with air from the left side only, will create a rarefaction of air in the angle $b d$. It is thus exposed to a one-sided pressure, and will therefore be deflected, as mentioned, and follow the curvature of the surface until it meets a counter current sufficiently strong to prevent a further rarefaction. If this view can be substantiated, it is plain that two external forces are acting upon the ball. One, the impact of the air-current at b , transmitted at right-angles to the surface, acts radially, and can be represented by the line $o p$. The other force, $o q$, is occasioned by the surplus pressure of the atmosphere on the lower side of the ball, over that of the rarefied zone under the curved current, and combined with $o p$ it forms the vertical resultant $\equiv r$, by which the weight of the ball is sustained.

Easy Experiments for Proofs.

The rarefaction of air under the deflecting current can be proved by the following experiments to the *Polytechnic Review*.

Cut a small hole, say one-half-inch square, in a card board, fasten over this hole a cover of the same material, by means of a strip of thin paper and mucilage, to form a valve, and bend both the card and the valve into a cylindrical form. If now a current of air is directed against the card, as shown in Fig. 5, the valve will open wide, showing the pressure under it to be greater than that above it.

Or take a strip of ordinary paper, about one inch to two inches wide, lay it over a cylindrical surface and blow against it in a nearly tangential direction. The end of the strip will then rise as shown in Fig. 6.

Quite a number of other experiments might be mentioned, showing the same facts.

The rotation of the ball is produced by the friction of the air-current passing over the ball, and is therefore a secondary result.

The phenomenon of deflection of a current when striking a convex surface can be brought to bear on geographical and meteorological facts. The Gulf stream follows the curved shore of the United States, for the identical reason that the ærial current follows the shape of a cylinder or a globe, and takes a course which otherwise it would not take. When a current of the higher strata of the atmosphere strikes the peak of a mountain it will be deflected, follow the sides of the mountain, and will sweep the valley.

New Leveling Target.

In the operation of spirit leveling in the work of the United States Coast Survey, and especially in the levelings made in connection with the observations for the determination of the co-efficient of refraction, several improvements have been made in the construction of the leveling rod, such as a slow-motion movement, means of correcting for temperature, etc.; but the ordinary target was retained, although imperfect.

Last season Professor George Davidson, of the United States Coast Survey, experimented upon ten forms of leveling targets proposed by observers. They were placed upon one rod, and the leveling instrument directed upon each successively at a given distance. This eliminated the weakest. At a specific distance, under tests, a larger number was laid aside; and at the third distance, of nearly four hundred yards, the target shown on this page alone remained clear, well defined, readily recognized and capable of affording the best results.

The long narrow line of white can be bisected by the horizontal thread of the level with the utmost precision; and, moreover, the least want of verticality of the rod is readily detected. On each side of the horizontal thread a clear line of white is exhibited and bisected with almost the same certainty that the graduation of a large theodolite is bisected by the two parallel threads of the microscope micrometer. The small white "lozenge" in the middle gives, at proper distances, a broader space over which the horizontal threads can be detected, while the broad vertical bands of white on the edges of the target serve a similar purpose when the horizontal thread is projected above or below the "lozenge."

In describing and showing the drawing of the target illustrated, at the last meeting of the California Academy of Sciences, Professor Davidson stated that, in the method of observing which he had adopted, extra precaution is used to avoid mistakes in reading off the vernier of the leveling staff. The rodman keeps a form of record, and when the observation has been made, he enters the reading therein. In going forward past the observer, the latter reads the staff, makes his entry, and then compares the records. When the observer moves forward with his instrument, he stops at the rodman's position, reads the staff, and compares his record with that of the rodman. In this way the probabilities of error in reading are reduced, and can be at once tested and corrected.

The target described is plain black and white, in the form shown on this page. The size is precisely similar to that used by Professor Davidson at four hundred yards. For greater distances, of course, a larger one could be used.

Our Lead Product.

The following interesting article on the lead product of the United States is copied from Edward A. Caswell's circular:

The Centennial year has passed away, and with it all its expected remunerative business and large profits; in place of which we have seen a somewhat limited sale of goods, shrinkage of values, unhealthy competition, and small entries on the profit side. The decline in gold of nearly ten per cent. has added to trials of importers and consumers, who purchased their raw material in coin, but at present writing, this variable, speculative and troublesome factor bids fair soon to disappear from merchants' calculations. With that point settled, the Presidential muddle cleared up, and confidence reassured, we may fairly hope for the long expected reaction in business, and the much talked of "better times."

Pig lead has, of course, sympathized with trade in general, except that its decline has been proportionally greater than that of other articles, owing to the fact that the price had been previously sustained by large capital in strong hands, so that to the normal fall was added the margin of factitious advance. Within ten weeks the actual currency decline was nearly \$20 per ton; at the same time base bullion only fell \$12 to \$15 per ton, showing pretty clearly that refiners must either have made very large profits previously, or else are now working nearly at cost. Every one familiar with the figures knows the latter supposition to be correct, and that bullion must decline or lead advance to afford a reasonable profit.

The United States product of 1876 exceeded that of 1875 by 3,967 tons and the supply of 1876 exceeded that of 1875 by 1,482 tons. Stocks throughout the country, January 1, 1877, were less by about 600 tons than in 1876, so that our consumption was apparently about 2,000 more last year than the year before, but it must be noted that about 4,300 tons of imported metal that figures in the supplies of 1876 were re-exported to Europe in the form of bullets, so that in reality the consumption fell off 2,000 tons, while with a fair demand and ordinary increase of trade, it should have been an increased consumption of six or eight thousand tons.

The year has been devoid of any peculiarly new features in lead, except that we have clearly shown our capacity for a domestic production, sufficient to render us entirely independent of any supply from foreign sources, and figures confirm the view that the supply must eventually be large enough to admit of exportation, for the mines thus far opened and worked, are so rich, added to the known and unopened rich deposits in Missouri and the Far West, that we may almost consider their capacity as illimitable; also the variety of sources is a guarantee of continuance which we would not have were we entirely dependent on two or three mammoth mines that might give out at any time. For although the superb Richmond and Telegraph mines together have turned out about one-sixth of the desilverized product, we can point to a dozen others that are scattered through Colorado, Utah, Montana, New Mexico and California, that also have work in sight for some years.

Utah at present far outstrips all other States in lead, has produced about three-fourths of the refined supply in 1876, and has even run ahead of Missouri, "by a large majority on a fair count." Missouri gave promise early in the year of yielding an enormous increase; but the output fell off toward the end of the year, and the total is but a few tons ahead of 1876. Galena on the contrary shows an increase of 25 per cent. Both Missouri and Galena are to-day unquestionably in far better position than ever before to increase production, having made judicious outlay of capital and introduced labor-saving appliances and more systematic methods of working.

In the Far West the lead interests are on a substantial footing and mainly in the hands of working men who know their business and use their own capital with that caution and judgment which did not characterize the policy of stock companies, having high salaried officers whose ignorance and reckless management ruined many good mines, and cast a shadow over mining investments, which are in reality as safe and remunerative as others.

The last year has shown the beginning of a competition between the argentiferous ores of the Far West and the virgin leads of Missouri, which will assume more serious character in the future. The Missouri ores are rich in lead, near the surface, and prepared at slight cost, convenient to lines of transportation and a market, and worked in such a manner as to incur no risk or loss to the owner, so that the production can only be checked when labor readily finds more remunerative employment in other occupations.

On the other hand, argentiferous ores carry less lead, are deep in the earth and must be extracted with greater risk at considerable outlay of capital, require an expensive treatment and pay high rates for transportation; but all these drawbacks are paid by the silver extracted, and render these ores dangerous competitors to Missouri.

The improvement in quality of leads used for corrosion has been very marked, and the desilverized brands have reached a standard that satisfies our most fastidious corrosors, and precludes further importation except at competition in price. Greater care and new methods in

smelting have improved the quality, and rendered more uniform the Cranby and several other brands of soft Missouri lead, and opened the way to an improvement in this respect which was greatly needed. It has also shown the Missouri smelters that the added cost of extra refining is more than covered by the enhanced price obtainable.

The Mendocino Gold Mines.

A reliable special correspondent gives the Sonoma Democrat the following: You have heard of the gold mines above Ukiah, near Calpella. Visiting them a few days ago I was astonished at the extent of the preparations to work them. The owners claim that in prospecting the gulch and surrounding hills that "the color" can be obtained almost anywhere; that the gold seems to be thoroughly distributed, and hence they conclude with the aid of hydraulic machinery they can be made to pay. Taking advantage of the living streams that form the headwaters of the Russian river, they are constructing an immense ditch seven miles in length. This ditch is to be five feet wide at the top, three at the bottom and two and a half feet deep. It has a fall of 12 inches to the mile. The entire length has been graded with the exception of a large tunnel near the lower end. It is a splendid piece of engineering. It winds around the hills, though rocky and rough, and at three points it plunges right through the hills. Two of the tunnels are short, but one of them is 600 feet long.

There are about 90 men at work, several miles of the ditch is completed and work on the remainder is progressing rapidly. When the water is brought in they will have a fall of from 50 to 100 feet—enough to tear the mountain from its base. The whole enterprise is in the hands of a company in San Francisco, who are furnishing the sinews of war. They have built a large hotel at Calpella, as if they expected the thing to last. Your correspondent traversed almost the entire length of the ditch with Mr. Holman, the Superintendent, as cicero. He was remarkably polite and communicative.

Just at noon we reached the upper camp and partook of a hearty dinner of boiled beans, beef and potatoes in regular miner style, eating off bare boards in a tin plate. The fare was excellent, especially with the sauce of appetite created by a walk of several miles. The work of constructing this ditch was commenced the first of last November, and the favorable winter has enabled them to push it forward with great rapidity. For one I never had much faith in gold mines in the Coast range, and should these prove productive I shall be surprised.

The Outlook in Eureka District.

The Sentinel says: The tendencies to an early and healthy revival of business are among the signs of the times to be noted among all classes in Eureka. There is no surer barometer of the prosperity of a community than the faces of the merchant and artisan, and all express themselves confidently as to the future outlook. An energetic and enterprising people, like ours, who have so long fretted at the general stagnation of trade, will be the first to take advantage of the favorable condition of the mining industries, and that there is a very perceptible change for the better, the most skeptical will acknowledge. Glancing over the field, we see all of the principal mines showing new developments and renewed activity. There is a certainty that more bullion will be produced during the next 12 months than in any previous year, and strong probability of there being a large addition to the working force. The rise of silver to its old standard operates greatly to our benefit, relieving the mines of an onerous discount on the precious yield. The districts in the eastern part of the State are in a healthy and flourishing condition, and Eureka participates in their general prosperity. The recent storm, though retarding hauling and coal delivery to some extent, will help the stock interests of the country and prevent the depletion or removal of herds to other points. Our agricultural interests do not figure very largely in our resources, but the recent acquisition of a portion of Pine valley swells it to quite a figure. We think we may safely prophesy that the coming season will be one of the most prosperous that this county has ever enjoyed.

THE LEACHING PROCESS.—From a gentleman connected with the Martin White company's mill the White Pine News gets the following report of the leaching process, now being experimented upon: "On the 1st of January steam was gotten up in the mill, and on the 10th the White furnace was fairly started; on the 14th the first ore pulp was put in the leaching barrels. Up to the 31st of January the results were: Ore average, \$26.40 (\$20 to \$40); chlorination, 47% (30% to 60%). The base metals not being chloridized are sent through in such a state that they are leached through with the silver, and so make exceedingly base bullion, of which only one or two pounds has been produced. As the leaching process depends entirely upon the furnace work, therefore no better results can be obtained until the roasting is bettered. Again, the attempts to manufacture the leaching liquors as yet are hardly perfected, and the mill is short of water. This latter defect is being remedied by bringing in one or two springs, and the assayer (Wagner) has lately succeeded in making the former. So the 20 days' run has been productive of some experience, and the ultimate success of the mill is almost certain."

AN IMPORTANT DISCOVERY.—Some time since says the Eureka Sentinel, Professor Stewart said there was no coal to be found in eastern Nevada. In spite of this decision, the Pancake coal mine continues to be worked with good results, and gives great promise for the future. We have now an important discovery to record. John S. Jones and William R. Huse have been prospecting for some time on the Pancake range of mountains, and have now struck it at a point on the Sullivan road, one and one-half miles west of the Pancake coal company's mine. The vein is two feet wide and of a quality of coal known as "binding coal," considered the best. The vein was struck after sinking a depth of 72 feet, and running a drift for the distance of 20 feet. The bottom of the under lead is blue sandstone and the top slate. The vein pitches to the southeast, and seems to increase in width as it is developed. Messrs. Jones and Huse have been prospecting in that locality for about a year. The above vein was struck one year ago. They are now engaged in extending the drift along the course of the vein.

10 STEVENSON STREET, S. F.

San Francisco Pioneer Screen Works,

J. W. QUICK, MANUFACTURER.

Several first premiums received for Quartz Mill Screens, and Perforated Sheet Metals of every description. I would call special attention to my SLOTT CUT and SLOTT PUNCHED SCREENS, which are attracting much attention and giving universal satisfaction. This is the only establishment on the coast devoted exclusively to the manufacture of Screens. Mill owners using Battery Screens extensively can contract for large supplies at favorable rates. Orders solicited and promptly attended to.

32 Fremont Street, San Francisco.

MENZO SPRING,

Manufacturer of ARTIFICIAL LIMBS,

Of 168 Tehama street, has removed to No. 9 Geary street; office, room 2, fronting on Market, opposite the head of Third street.

ERICH G. GAERTNER,

MINING ENGINEER.

All classes of mining properties reported on, consultations had on reduction of ores of all descriptions, plans for furnaces and reduction works furnished, and the construction of them superintended. Ore tests made at the office.

309 California Street, Rooms 8 and 9.

Iron and Machine Works.

PACIFIC ROLLING MILL COMPANY,
SAN FRANCISCO, CAL.

Established for the Manufacture of

RAILROAD AND OTHER IRON

—AND—

Every Variety of Shafting.

Embracing ALL SIZES of
Steamboat Shafts, Cranks, Piston and Con-
necting Rods, Car and Locomotive
Axles and Frames.

—ALSO—

HAMMERED IRON
OF EVERY DESCRIPTION AND SIZE

Orders addressed to **PACIFIC ROLLING MILL COMPANY**, P. O. Box 2032, San Francisco, Cal., will receive prompt attention.

The highest price paid for Scrap Iron.

THE RISDON

Iron and Locomotive Works,

INCORPORATED.....APRIL 30, 1868
CAPITAL.....\$1,000,000.

LOCATION OF WORKS:

Corner of Beale and Howard Streets,

SAN FRANCISCO.

Manufacturers of Steam Engines, Quartz and Flour Mill Machinery, Steam Boilers, Marine, Locomotive and Stationary, Marine Engines (High and Low Pressure). All kinds of light and heavy Castings at lowest prices. Guns and Tappets, with chilled faces, guaranteed 40 per cent. more durable than ordinary iron.

Directors:

Joseph Moore, Jesse Holladay, C. E. McLane,
Wm. Norris, Wm. H. Taylor, J. B. Huggin,
James D. Walker.

WM. H. TAYLOR.....President

SAN FRANCISCO.

AMERICAN MACHINE

AND

Model Works

Experimental and fine Special Machinery, Dies, Taps, Punches, Reamers and other tools made to order. Planing, Gear Cutting, Machine Repairing, etc. Models and Patterns for Inventors promptly executed, in wood or metals.

I. A. HEALD, 514 Commercial St.
Between Sansome and Leidesdorff Sts., San Francisco.

PHELPS MANUFACTURING COMPANY

Manufacturers of all kinds of

Wharf and Bridge Bolts, Railroad Trestle Work, Car Frames and Bolts, Machine Bolts, Set Screws and Tap Bolts, Lag or Coach Screws.

ALL STYLES OF FANCY HEAD BOLTS.
HOT AND COLD PRESSED HEXAGONAL AND SQUARE NUTS, WASHERS, BOLT ENDS, TURNBUCKLES, ETC., ETC.

13, 15 & 17 Drumm St., near California,
SAN FRANCISCO, CAL.

SACRAMENTO BOILER WORKS,

37 Fremont St., cor. Mission, S. F.

HALL & KELSHAW,

PRACTICAL BOILER MAKERS,

Marine, Stationary and Portable Boilers, Smoke Stacks, Hydraulic Pipe, Oil or Water Tanks, Ore and Water Buckets, Gasometers, Girders, Bridges and Iron Ship Building.

ALL KINDS OF SHEET IRON WORK.

Repairing promptly attended to at the lowest possible terms.

CALIFORNIA BRASS FOUNDRY,

No. 125 First Street, Opposite Minna,
SAN FRANCISCO, CAL.

All kinds of Brass, Composition, Zinc, and Babbitt Metal Castings, Brass Ship Work of all kinds, Spikes, Sheathing Nails, Rudder Braces, Hinges, Ship and Steamboat Bells and Gongs of superior tone. All kinds of Cocks and Valves, Hydraulic Pipes and Nozzles, and Hose Couplings and Connections of all sizes and patterns, furnished with dispatch. PRICES MODERATE.

J. H. WEED.

V. KINGWELL.

ASBESTOS COATING

For Steam Boilers, Pipes, etc. Best non-conductor of heat in use. It effects a LARGE SAVING OF FUEL, LASTS AS LONG AS THE IRON to which it is applied, and is reasonable in cost.

THE O'HARRA

CHLORIDIZING FURNACE

Guaranteed to Chloridize from 85 to 95 per cent. of any gold or silver ores that are not more profitable for smelting. Will also desulphurize ores and put them in proper shape for working in cupola furnaces.

Cost of Roasting and Chloridizing by this Process:

Two cords of wood at \$6.....	\$12.00
Two firemen at \$4.....	8.00
1,500 lbs of salt at 14c.....	22.50
Wear of shoes and power.....	1.50

Cost for 15 tons.....\$44.00
Cost for one ton.....2.93

In a furnace of three or four times this capacity the cost is decreased by 20 per cent.

The furnace is now working successfully at the Poe Consolidated Co.'s mines, in the Peavine District. For further information, apply to

D. J. O'HARRA,
Reno, Nevada.

The Ingersoll Rock Drill

Is Extensively Used in the East and

TAKES THE PLACE OF ALL OTHERS,

Wherever introduced, because it can be run with less power, labor and repairs, and do more work than any other Drill in the market. It has but few parts, is easily handled, being light, and has AUTOMATIC FEED, which saves labor. WE ASK FOR TRIAL AGAINST ANY COMPETITOR. For particular information regarding Drills or Air Compressors, send for circular to

The Great Western Scroll Saw Co.'s new and improved \$5.00 Foot and Steam Power Scroll and Bracket Saw is the best one yet invented. With it men and boys are making from \$3 to \$10 per day. We will send you a Machine, six Saws, 15 Patterns and two feet of prepared wood, on receipt of \$5. Address,

GREAT WESTERN SCROLL SAW CO.,
Leavenworth, Kansas.

\$55 to \$77 a Week to Agents. \$10 Outfit Free. P. O. VICKERY, Augusta, Maine.

Continued from page 117.

ELY DISTRICT.

ALPS MILL.—Pioche Record, Feb. 10: The Alps mill started up on Sunday last and has been running steadily on custom ore during the week, although there is quite a lot of ore on the platform from the Alps mine. There is a quantity of chlorides ore there awaiting milling, and several lots from Leeds, Utah. While we were at the mill on Friday we witnessed the casting of a couple of bars of bullion, valued at about \$2,300.

FOR EL DORADO CANYON.—Several members of the company in Pennsylvania, who purchased mines down in El Dorado canyon, in the southern part of Lincoln county, and who have been stopping in Pioche for the past eight weeks, left town yesterday for that section. We soon expect to hear a good account from that portion of the country, for it has been a well-known fact for the last two years that there are some very promising mines at El Dorado.

Arizona.

PROSPECTING.—Arizona Miner, Feb. 9: A. W. Callen has recently been prospecting through the mountains and had the good luck to drop on a lead, which, from its magnitude, richness, etc., he has named the Giant silver mine. It is in the Peck district, where there are already some of the best paying mines in Arizona, and those that have been prospecting to that extent so as to leave not the least doubt as to their permanency, and Mr. Callen has, no doubt, just as good a discovery as any in the district.

T. M. ALEXANDER, one of the owners in the famous Peck mine, arrived from Alexandria yesterday and he reports everything at the mine as looking better than ever before.

THE TOP.—D. C. Thorne has shown us a certificate of a pulp assay of 13 tons of ore from the Tip Top mine in Humboldt district, near Black canyon. The assay is by Blake, and shows \$678.62 per ton in silver and \$11.30 in gold.

LUKE'S MILL.—C. A. Luke has purchased the Constanca mill, near Ehrenberg, which is rigged as a first-class 10-stamp gold mill, the finest perhaps that ever came to Arizona. It was bought by Dr. W. W. Jones, in 1870, to work the Constanca mine, and put up one mile from Tyson's Wells. The mill originally cost \$45,000. Mr. Luke has also purchased in San Francisco, pans, settlers, etc., to convert it into a complete silver mill, and will move the whole thing into Bradshaw basin, where it will be set up and put to work on ore from the mine of Luke & Co.

THE SILVER PRINCE.—D. K. Houghtelin this morning showed us the plat and field notes of the Silver Prince mine, as surveyed by E. D. Thomas, Deputy U. S. Mineral Surveyor. The entire claim contains 10,977,1000 acres, having been located about 50 feet short of the 1,500 feet. Houghtelin & Curtin have recently taken out considerable ore from a ten-inch pay streak where they originally found the extraordinarily rich ore. They are ascertaining what is now coming out into two classes, and a day or two ago sampled up the dumps and found their first-class worth by average assay, \$2,500 per ton, and the second-class something over \$800. Meyers & Henderson, who have a lease on a portion of the claim, have out about a ton of \$1,400 ore.

Idaho.

SOUTH MOUNTAIN.—Idaho Avalanche, Feb. 17: A new pump has been ordered wherewith to carry on operations in the Bay State mine. The old pump was insufficient for keeping the water out, and operations have consequently been suspended until the arrival of the new pump. The miners have been paid off up to the first of February. This will enable them to settle a portion of their indebtedness and make a fresh start.

GOLDEN CHARIOT.—At the Golden Chariot operations are being vigorously prosecuted and everything wears a very hopeful look. A large quantity of high grade ore has recently been taken out from the stopes, and from every section of the mine the indications are very promising. The winze between the 6th and 7th levels is down 28 feet, and the developments all the way through are of the most promising character. Some rock has recently been encountered which assays \$300 to the ton in silver, and all the indications here point to the existence of a very valuable ore body in the immediate vicinity. The prospects of the Chariot were never better at any previous stage of development.

FLINT DISTRICT.—We understand that parties in San Francisco are making an effort to revive work in the Flint district the coming season. Fred. Warnke is reported to be taking an active interest in the matter. Flint was a lively camp once, and even a man who invested money there profited by the operation. None of the rock was extravagantly rich, but it always paid well, and the mines of that section are just as good now as they ever were. There is still abundant machinery in the old camp for crushing the rock and practical men who are intimately acquainted with the mines there have no hesitation in saying that there is not a more promising spot in the country.

WAGONTOWN MINES.—The prospects of the Wagontown camp continue to be regarded as very favorable, the best evidence of which is found in the desire displayed by many to become interested in the leading mines of that camp. Only a small amount of work has been done on the Henrietta the past few months, but the rock taken out reveals marvelous richness, comprising in many instances chunks of almost solid metal. A quantity of rock recently taken from the Lepley mine was sold for \$300 a ton on the dump. Favorable reports also come from many other mines. The Jones & Adams mill has recently been crushing rock from the St. Clair, Webfoot and Stoddard, and in each instance we understand with satisfactory results.

Work is progressing on the main shaft at the Belle Peck, where the ledge continues to improve as the work of development progresses. The Potosi is looking fine and there is a large quantity of rich rock on the dump awaiting crushing.

Utah.

LITTLE COTTONWOOD.—Salt Lake Tribune, Feb. 15: For some months past Walker Bros. have been, in part, working the Antelope and Prince of Wales mines, in Little Cottonwood, by what they call the tribute system. That is, they allow the miner a certain per cent. of the ore he takes out, and have their own superintendent supervise the work, so that the developments made shall be of a substantial character. A quantity of rock recently taken to the owners and the workman, as both find it to their mutual interest. Since the system has been in vogue it is said the miners have averaged \$5 a day each, and the prospects are it will become a popular method of working mines of high-grade ore in narrow veins. Ore is being shipped out of Little Cottonwood at the rate of 127 tons daily, with a prospect for a speedy increase the coming season. On Ensign, all there is hardly enough to make good sleighing, there being only about three feet on the level. The road in many places has to be repaired by filling it in with snow, so as to render it passable for sleighs. The present winter in Little Cottonwood has been the lightest ever known there, and the weather has been continuously delightful. An exceptionally early spring is anticipated, and heretofore the great body of snow has fallen before the 1st of January. The camp is lively, and flush times the coming season are universally expected.

The Central Pacific Railroad Company has recently purchased the marsh land extending from the south line of Bay View homestead to the San Antonio estuary, on the other side of the bay. It is surmised that this purchase, which adjoins the railroad company's 60 acres of upland at Oakland Point, is intended to be the site of a portion of the railroad workshops and also a rolling mill.

PATENTS AND INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

FOR WEEK ENDING FEBRUARY 13TH, 1877.

EARTH AUGERS.—George Watson, Oakland, Cal.
SHEEP SHEARS.—William George, Modesto, Cal.
HARVESTERS.—Edward D. Stewart, Wheatland, Cal.
FRUIT DRIERS.—Russell B. Blowers, Woodland, Cal.
UNDERGARMENTS.—Coelia C. Curtis, S. F.
SHACKLES.—Henry William Dilg, Portland, Ogn.
COMPENSATING CRANKS.—Robert D. Milne, Santa Barbara, Cal.

MITER MACHINES.—John P. Tierney, Sacramento, Cal.

TRADE-MARKS.

BORAX.—Smith Brothers, S. F. and New York, N. Y.

The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue.

NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of mention:

FRUIT DRIER.—R. B. Blowers, Woodland, Yolo county. This fruit drier is more especially valuable as an assistant in curing raisins which have been partially dried in the open air, but have not been completed because of bad weather. It is adapted, however, to all classes of fruit. It consists of a series of rooms provided with cleats to receive sliding trays, which are especially arranged to cause the currents of hot air to pass over them in a peculiar manner from above. These rooms are arranged on each side of the central heating apparatus, and are provided with transom doors by which the heat is admitted or cut off, as may be desired. The hot air, after doing its work, escapes through openings in the bottoms of the chambers into parallel flues which open into a central chimney of sufficient height to produce a proper draft. Each drying chamber is provided with doors opening outwards and any number of them may be used or cut off at will by simply closing the hot-air gates. In curing grapes for raisins it is well known that the best product is obtained by open air or sun drying, and this can only be accomplished in climates which are rendered very dry by reason of long, rainless seasons such as occur in California and some other parts of the United States. A great difficulty is however encountered from the fact that the season when the grapes are in proper condition to be cured is so near the border of the rainy season that the half-cured fruit is often caught by the early rains; and, although it may be covered and protected from the direct injury of wet, yet the atmosphere never becomes dry enough again to complete the curing of the raisins. This sun drying is therefore supplemented by the addition of artificial heat, and it is necessary at the same time that the fruit should be handled as little as possible from the time it is picked until packed in boxes. To effect this the inventor has devised this peculiar style of drier.

"COMPENSATING CRANK."—Robert D. Milne, Santa Barbara. The object of this invention is to provide a novel method for the conversion of reciprocating rectilinear motion into rotary motion by a mechanism, by means of which the inequality of crank power is equalized and balanced in such a manner that the direct pressure of a piston or other motor is transferred to the crank with greater uniformity of action than in the case of an ordinary crank. The mathematical principle of the invention consists in producing a series of changes in the line of direct propulsion, as it affects the crank, so that the point of impact or force approaches or recedes from the center of the crank during its revolution; this point of impact being furthest from the center of the crank at the beginning and end of stroke and nearest at the middle of the stroke. The invention is also designed to utilize the independent motion of the connecting-rod thus acquired, by bringing it to bear upon the crank at such angular inclination as to be equivalent to direct propulsion in a line varying from the line of force inversely as the angle which the connecting-rod makes with the crank varies from a right angle. The novel points of the invention are the applications of the mathematical principle defined above to the matter of crank motion, and also the mechanical means which are employed to accomplish that end.

UNDERGARMENT.—Coelia C. Curtis, Oakland. This is an improved undergarment for female wear. The invention relates to a mode of cutting and forming that class of undergarments for female wear, in which the waist and drawers form a single garment. It consists in forming the entire garment, with the exception of the sleeves and back of the waist, in two pieces or parts, each of which pieces or parts form one

leg and one side of the waist front, thus economizing in material and labor. The back of the waist is cut on which is known as a "sacque style," so that it will fit the person more comfortably and snugly. This provides a complete and convenient garment which is cut in the most economical style and without waste.

MITERING MACHINE.—John P. Tierney, Sacramento. This invention relates to certain improvements in mitering machines, these improvements being more especially adapted to a machine for which letters patent were granted to the same inventor in August, 1873. It would be impossible to give an intelligible description of this invention without the aid of engravings.

Academy of Sciences.

The regular meeting of the California Academy of Sciences was held on Monday evening last, President Davidson in the chair.

The following donations to the cabinet were received: From Professor Davidson, specimens of earth showing the cell-work of the white ant of India, collected in April, 1875; *Coleoptera* from the tomb of Sokwra, Memphis, Japan and Sierra Nevada mountains.

From Henry Edwards, *Chirus pictus* from San Francisco market; and from W. Murray, batrachians, locality San Francisco.

From Colonel Gray, Chief Engineer of the Southern Pacific railroad, fresh-water bivalve, fossil and marine shells from the Colorado desert; presented with some remarks by that gentleman, who stated that they were found at a point about 250 feet below the level of the sea. This was another evidence of that desert having once been an arm of the main.

From Eugene Gillespie, United States Consul at San Jose del Cabo, Lower California, specimens of seeds and flowers. It was stated, in connection with this donation, that arrangements would be made by which the Academy would receive a number of interesting plants from Mr. Gillespie.

Mr. F. T. Newbery presented the following, received from Mr. Cheeseman, Curator of the Public Museum at Auckland, New Zealand: Four specimens of vegetable caterpillar; a fungus (*Cordyceps Robertsii*), parasitic on the larva of the moth *Hepialus Vireceus*; eight portions of the eggs of the gigantic moa bird, and four boulders used by that bird in assisting its digestive function; three stone adzes; four specimens of siliceous deposits of maize cob, with siliceous incrustations, from Rotamahana; specimens of New Zealand flax, both hand and machine dressed, and cloth manufactured from that flax, together with specimens of ramie fiber.

Mr. Newbery called the attention of the Academy to a collection of moa bones in the possession of the Curator at Auckland, and suggested that the Academy communicate with the owner as to the terms of their disposition. He also read a paper on the

Vegetable Caterpillar.

Which he found while surveying in New Zealand. It is a fungus, found standing at the height of three or four inches above the level of the ground, and a good specimen was procured by digging. It was found in a vertical position, with the head uppermost. In the fresh specimen, the marking of the ordinary structural appearance of the living creature was beautifully apparent. The stock was round, with a curious furry ornamental top, more or less developed. The interior of the stock was white, in fiber like the crust of a cocoon. These evidences indicated that at some time the creature belonged to the animal kingdom, and that theory was countenanced by authorities. If this point should be conceded, it would be a curious matter for speculation and investigation as to how this larva, whilst in the course of nature, and buried three inches beneath the surface of the earth, was seized by a parasitic plant, changing its nature, causing it to become a vegetable organism in its entirety, without undergoing any ordinary process of disintegration or dissolution.

Tattooing.

Mr. Newbery also presented some photographs of New Zealanders, illustrating the effects of their tattooing, and described the process. It is done with a chisel and mallet, and is a slow and tedious operation, requiring several days. It is extremely painful, the most sensitive parts being the temples and eyelids. Women are suffered to tattoo the lips and chin only, but the men are not restricted. One side of the face always corresponds with the other, no matter how intricate or elaborate the design. The curves and lines are very graceful. The chiseling sometimes extends over the whole surface of the body. Of late years the process of tattooing has been neglected, on account of the natives' increasing appreciation of European manners and customs.

Professor Davidson read a continuation of his series of papers on irrigation in India, Egypt and Italy.

He also described a new leveling target used by the Coast Survey, which is more fully referred to in another column of this issue.

A CORRESPONDENT of the Western Associated Press at Calcutta says: The Viceroy's official dispatch of February 16th states that the famine in North Ancol is much worse than supposed, and there is great distress in Mysore.

[Copyrighted.]

Mechanical Ore Concentration and Separation—No. 23.

[Written for the Press by FRANCIS M. F. CAZIN, M. E. Santa Fe, New Mexico.]

Before entering on the description of the operation of separating slimes into the different materials by quality, I should here again draw the attention of the reader to the fact that, although in all cases where the presence of a difference in specific gravity makes such mechanical separation applicable, such separation forms the most economical mode of operation with all classes of ores preparatory to reduction.

It therefore is not true that mechanical separation is economical and profitable in all its stages. It is the most economical mode of treatment, as above stated, as long as the sizes of grains and sands form the object of separation; but when slimes are the object, it deserves a close examination to ascertain whether a direct (chemical) reduction may not be the better mode of operating. This is because slimes are of such a degree of minuteness as to require some of the reductive operations, as, for instance, roasting, leaching, or amalgamation. It should be mentioned here that the mill practice of California and Nevada has contributed largely to locating the limit where the milling of slimes is more profitable than dressing far ahead of a place where European practice would stand in favor of mechanical separation; and this is a decided progress attained by the ingenuity of American mill-men.

But the fact is, that American practice is to treat as slimes what might, for one-half or one-quarter of the expense, be treated as grains or sands. This persistence in treating ores as slimes results in obtaining a lower percentage of valuable parts than might be obtained otherwise. This American practice is indeed almost a public calamity, because it results in large losses of valuable mineral, which would otherwise benefit not only the owners of large and important mines, but the world at large.

This will in time be obviated by the continual desire of enlarging the capacity of the existing works, when it will be found that with the present mill capacity, two, three or four times the product can be worked in preparing the ore for the mills by concentrating the waste rock out of the grain and sand sizes, and letting the mills work all the slimes resulting in dressing the total mechanically, but made richer by stamping only the concentrated grains and sand without the waste rock; which rock may be so easily dispensed with without material loss, and at comparatively much lower cost in dressing grain and sand sizes.

The operating on a good jig on grain and sand sizes results, not only in clean concentrated ore and in waste rock. A good jig should and does also save, as a separate product, such particles of rock to which a particle of metallic ore still adheres. The specific gravity is by such a particle influenced sufficiently to permit a hesitancy of motion in comparison with clean rock particles; and such hesitancy is sufficient to let them be saved. It is a great mistake usual in practice to refeed these particles of mixed constitution to the jig-sieves. They should be invariably delivered to the stamps or pulverizers, so as to break their particles into the different qualities. Thereafter they may be treated with success as slimes, as well where these slimes are subjected to further mechanical separation, as where they form the material for direct reduction.

MONTANA MINES.—The Butte Miner has the following Phillipsburg items: The Northwest company's mill has been shut down and the hands which have had employment there have been discharged. The reason for stopping these works is said to be from the want of ore, the capacity of the mill being much greater than the supply of ore that can be taken from the mine until further development is made and another shaft sunk in order to bring the ore to the surface, there being at present only one outlet for the ore. The Hope mill still runs quite successfully. There is plenty of ore on hand and more in sight and the yield from the ore has been very satisfactory. The Algonquin mine, which lately has passed into the hands of Eastern capitalists, is being developed by a force of 15 men. A tunnel has been run into the side of the hill which strikes the lead at a depth of 80 feet below the surface, and from this point levels have been run each way to a distance of about 60 feet, where sinking upon the lead has been commenced. The lead as far as developed shows very favorably. The width of vein matter at places is quite large but the average is probably a little over six feet. The ore is argenteous galena carrying a high per cent. in silver. Both walls are met with and are well defined. The mine has been well timbered throughout and is in a most excellent condition for future operations.

RUSSIA has 600,000 men, or two-fifths of her army, organized. About half are on the frontier, ready to begin operations. The Russian army south of the Caucasus, on the Asiatic frontier of Turkey, is in readiness for action. It numbers 115,000 men, with 35 field batteries and 250 heavy siege guns.

WOODWARD'S GARDENS embraces an Aquarium, Museum, Art Gallery, Conservatories, Tropical Houses, Menagerie, Seal Ponds and Skating Rink.

Testing Roasted Silver Ore.

(Written for the SCIENTIFIC PRESS by C. H. AARON.)

The usual way of testing the percentage of silver chloride in roasted ore is by lixiviation with a cold solution of sodium hyposulphite. I have long suspected that this test was not altogether reliable, and some experiments which I have made seem to sustain the suspicion. These experiments were as follows:

1. Roasted ore containing silver to the amount per ton of \$65.00
 - A. Leached with ammonia, retained, per ton 13.20
 - B. Leached with solution of sodium hyposulphite, retained, per ton 5.20
2. Roasted ore, containing, per ton 60.00
 - A. Leached with ammonia (after digestion for several hours in warm ammonia), retained, per ton 15.00
 - B. Leached with sodium hyposulphite, retained, per ton 3.50

3. Sample of tailings containing silver to the value per ton of 9.00
 - A. Washed on filter with cold water. Filtrate contained Cl, but gave no metallic precipitate with solution KS.
 - B. Washed with hot water. Filtrate contained neither Cl nor heavy metal.
 - C. Washed with cold solution of sodium hyposulphite. Filtrate treated with KS gave a copious brown precipitate containing Ag, Pb, As, Fe, etc.
 - D. Excess of KS was added to filtrate C and to prevent resolution of As, a little Fe SO₄ also (in slight excess), then HNO₃ to decompose the sodium hyposulphite. A white precipitate was slowly formed, which on boiling became yellow (sulphur).
 - E. Precipitate from D removed by filtration and filtrate treated with an acid solution of Ag NO₃ gave no precipitate.

The inference is that the metal salts contained in the tailings, and dissolved by means of sodium hyposulphite, were not chlorides.

4. Sample of tailings, containing silver, per ton \$4.00
 - A. Washed on filter with hot water. Filtrate tested with barium nitrate showed SO₃; washing continued till no more SO₃ was found.
 - B. Washing repeated with hot solution of Na Cl (free from SO₃). A portion of the filtrate tested with KS gave a metallic precipitate; the remainder, tested with barium nitrate, showed SO₃ strongly.

The inference is that the metal salts extracted by Na Cl were sulphates, and as the silver is extracted by hot brine about as perfectly as by sodium hyposulphite, it seems probable that these metals exist as a multiple sulphate, otherwise the silver sulphate would have been extracted by hot water alone. The tailings gave no appreciable Ag Cl by treatment with ammonia. The metals extracted by hot brine are very slowly reduced by metallic iron, so that a good result is obtained from ore in this state, in pans, only by long continued working, and a base bullion is obtained, while the addition of lime to the pulp, intended to produce finer bullion, entirely prevents the reduction, causing richer tailings; whilst with silver chloride even a great excess of lime does not impede reduction nor prevent amalgamation, though the latter is somewhat impeded. By longer roasting of the ore the formation of silver chloride was improved.

An Elevated Railway for San Francisco.

San Francisco is to have an elevated prismoidal railway shortly; at least the preliminary steps have been taken in that direction. At a meeting of the Board of Supervisors on Monday an order was presented to grant a franchise to J. S. Kohn and his associates to construct, maintain and operate a prismoidal railroad on Market street and such cross streets as may give a continuous line to the ocean beach by way of the Golden Gate park, and thence southerly to the city and county line. The order defines the route as follows:

Commencing at the ferry landing on Market street and thence running along the southerly line of Market to Valencia, at a height of not more than 14 feet above the curb line, and thence in a westerly direction to and along and over such streets as are or may be opened to the entrance of Golden Gate park, being on and along and across on the south side of the entrance to the park on Baker street; thence along and near the south line of the Golden Gate park in a westerly direction to the ocean beach, and thence along said beach to the city and county line, with a branch road commencing at or near Fifth avenue, and thence by way of the Laguna Honda to the Laguna de la Merced, over the most feasible route, and thence easterly to the intersection of the line crossing in a southerly direction and along the ocean beach, and thence in a southerly direction to the southern boundary line of the city and county. Also, commencing at a point on the southern boundary line of the city and county of San Francisco, at or near San Miguel station, and running in a northerly direction along such lines and lands and on such streets as may hereafter be established, by any grade hereafter adopted, to the westerly line of Valencia street, and thence along said line of Valencia street to its intersection with the southerly line of Market street.

Section 4 prescribes that the road on Market street shall be built on elevated posts and pil-

lars of not more than 12 feet span, so that the prism or chord shall not be less than 14 feet above the top of the curbing, except at such places as the Board of Supervisors may give permission to build lower. The posts or pillars shall be securely imbedded in the curbing of the sidewalks.

The company proposes to propel trains by steam or compressed air engines, all locomotives to be supplied with spark-arresters and not to blow off steam-whistles in the built-up portion of the city.

The order prescribes the rates of fare as follows: From each passenger to and from any point between the eastern terminus and Scott street, five cents; between Scott street and Fifth avenue, on the south side of Golden Gate park, five cents; to and from any point between Fifth avenue and the ocean beach, 10 cents, and along the ocean beach to or from the county line, and on the branch road to and along the beach, 20 cents. From the county line to the westerly line of Valencia street, 10 cents; thence along Valencia street to the intersection of Market and Valencia streets, five cents.

The order gives the company the right to construct the railway over and across the sidewalks whenever necessary to run their engines and cars into and out of the depots.

Section 9 provides that the privileges and franchises shall continue for 25 years, to date from the completion of the railway, provided that two miles of said railway shall be completed within one year from the passage of the order, and the entire "line" be completed within five years from the passage of the order. The order was referred to the Street Committee.

Items of Interest from the Mines.

We give below items of interest from prominent mines, most of which are collated from letters of the respective superintendents on file at the offices in this city. Considerable of this news is later than that procured from the interior journals:

The average assay of car samples of ore from the Chollar is \$26 per ton. They are making three feet a day in sinking the South Comstock shaft.

The water in the Savage keeps the pumps busy to simply keep even with it. The news from the Golden Chariot (Idaho) is still encouraging. The bunches of ore encountered assay very well.

The mill at the Grand Prize started up Monday, and is running well.

Letter of the 17th, from the Eureka Consolidated, says: Since last report, the developments in the mine are of a very satisfactory nature, and no fear is entertained but what a steady improvement will follow as the work proceeds. During the week, the explorations made on 9th level, in connection with those made in other portions of the ground, will firmly establish the reputation of the mine and make it one of the most valuable in the district.

Both furnaces and mill of the Tybo are running steadily.

Connection between the Savage and Hale & Norcross mines has been made by the 1900-foot drift.

The south cross-cut in the Overman shows the quartz on the 1200-foot level to be 46 feet wide near the Caledonia line.

The last clean-up of the Eureka (G. V.) mine was 210 ounces of amalgam.

The north upraise—600 feet—of the Justice is now developing a well-defined body of ore, containing rich black sulphurets.

The water is all out of the main incline of the Indian Queen, and a part re-timbered. The incline was caved in several places.

The Manhattan mill reduced, last week, 141 tons of ore, valued at \$26,213.

The miners in the Exchequer mine, Alpine county, are on a strike. Cause—difficulty with the manager.

The Eureka Sentinel of the 18th says: "The decision of Judge Cole, in the late mining suit, by no means terminated the proceedings on injunction, as many thought. The case will be brought up again this week with the Richmond mining company of Nevada et al., as defendants."

THE ISTHMIUS CANAL.—The latest rumors concerning the isthmus canal are not favorable to its speedy construction. It has been reported that the government of Nicaragua has given a franchise to Harry Meigs, the railway builder, and that he has gained it merely to cut off the enterprise from other hands and not to accomplish the work himself. Another report denying the foregoing, states that the government of Nicaragua is determined to make the canal a source of profit for all time and will levy such restrictive taxes upon it that no one will undertake the project. If Nicaragua adopts any such policy as that it will be standing directly in her own light so far as success and development are concerned. It is to be regretted that a little sunshine country on the isthmus should so conduct itself as to stand in the way of a work which will be of advantage to all the world. We are not lawyers, but we cannot see why some sort of an international congress could not condemn the route and then lay it open for public benefit. But the matter is not settled yet. We only give the prevailing rumors.

THE damage by fire to the St. Louis bridge across the Mississippi will not exceed \$50,000.

General News Items.

MR. WORTMOUGH, Pay Inspector in the Navy, is appointed Paymaster General.

A HEAVY storm has prevailed for several days at the mouth of the Columbia river.

A BOARDING house for women only is about to be opened in this city. It is intended especially for the accommodation of girls who are sent in from the country to attend school.

THE rinderpest has appeared at Hull, England. It cannot be traced to contact with infected cattle. The strongest measures are being taken to prevent an outbreak.

THE Health Officer is prosecuting people for misdemeanor who do not report small-pox cases. Several aggravated instances of concealment have transpired within a week.

FIVE car-loads of machinery from Cincinnati have been received in this city and will be sent to Melbourne by next steamer for exhibition at the international exhibition in Australia.

OUR export trade during the first 15 days of the current month amounted to \$1,932,700, of which \$1,781,400 was in wheat. For the corresponding period in 1876 the total was only \$1,037,500.

THE Board of State Prison Commissioners on Saturday accepted the boilers, engines and shafting in the new workshop of the prison. All the bills presented were ordered paid, leaving a balance of \$50,000 out of the \$200,000 originally appropriated by the Legislature. This money will be used in building additional cells in the prison.

JUDGE DWINELLE, of the Fifteenth District Court, filed an opinion on Monday adverse to the city in the suit brought against it by the Spring Valley Water Works. The suit relates to the payment of a contested bill of \$92,000, which Auditor Ashbury refused to audit. The council for the city and county will at once appeal the case to the Supreme Court.

Wonder Quicksilver Mines.

During the past year, the Consolidated quicksilver mining company have expended about \$3,400 in the working and prospecting of the mine. About 150 feet of tunneling penetrates the hill, and cuts through a portion of the ledge beneath the Queen Victoria croppings. Another tunnel, 150 feet long, is run into the Doctor's Wonder, through streaks of cinnabar. A shaft is sunk 50 feet on the Queen Victoria ledge. There is a kiln of 40,000 brick, owned by the company and deposited near the claim, to be used in the construction of a furnace, as soon as the cash payments due for pool stock are in the treasury.

The \$3,400 already disbursed was raised by the sale of shares and by assessment No. 1. The following statement represents the present financial condition of the company: Cash on hand, \$452.56; balance due for pool stock sold, \$1,358.42; total, \$1,810.98; less present indebtedness for merchandise and labor, \$603.02; balance in favor of company, \$1,207.96.

The prospects of the mine are encouraging to the stockholders. The present foreman is an expert at the work assigned him, and he is performing his duty well. The croppings on the west wall of the Victoria ledge are rich in cinnabar and antimony, and it is presumed the tunnels will strike bonanzas when they reach the ledges. The work on the shaft is at present stopped on account of water. We look for this mine to be well developed the present year, and trust all the stockholders will grow rich enough out of it to snap their fingers with indifference to the probable effects of the dry season.—*San Benito Advance*.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's office at San Francisco.

MURCHIE G. & S. M. Co.—February 16th. Location: Nevada county. Capital stock, \$1,000,000. Trustees: Andrew Murchie, Robt. M. Fryer, S. F. Murchie, W. H. Smith, A. H. Eddy, F. H. Wells, W. H. Murchie, Robt. L. Tracy, F. Madge and E. G. Frend and J. B. Meeks.

SAN JOAQUIN AND SAN FRANCISCO WATER WORKS Co.—Feb. 16th. Object: To supply the city of San Francisco and other cities. Capital stock, \$20,000,000. Directors: H. B. Tichenor, Wm. T. Coleman, John O. Earl, Wm. B. Hyde, H. D. Bacon. This corporation will endeavor to sell certain privileges to San Francisco, being one of the competitors in the field against the Spring Valley.

WIDE AWAKE PROSPECTING AND M. Co.—Feb. 21st. Location: Arizona. Capital stock, \$1,000,000. Directors: H. M. Cameron, C. E. Lloyd, Christopher Queen, Joseph Goyette, James L. Cogswell, W. H. Roberts, Aaron Bunker, S. Sturgis, R. D. Manzy.

GLOBE GASLIGHT CO. OF NEVADA.—Feb. 19th. Capital stock, \$1,000,000. Object: To supply gas in all parts of Nevada. Trustees: J. J. Palmer, Wm. N. Meeks, Israel W. Knud, Chas. B. Kendall and John B. Meeks.
